Declaration of authorship

I certify that the work in this thesis has not previously been submitted for a degree nor has it been submitted as part of requirements for a degree except as fully acknowledged within the text.

I also certify that the thesis has been written by me. Any help that I have received in my research work and the preparation of the thesis itself has been acknowledged. In addition, I certify that all information sources and literature used are indicated in the thesis.

Acknowledgement

First and foremost I would like to express my sincere gratitude to my academic supervisor, Prof. Alex Novikov, who offered me a unique opportunity to study at UTS, as well as my industry supervisor, Prof. Pavel V. Shevchenko, who has provided tremendous guidance throughout. Every aspect of this thesis has benefited from their supervision. They have kept me on a straight path to finish my thesis, helped me to avoid publication pitfalls, and provided feedback when progress stagnated.

I gratefully acknowledge the funding sources that made my research possible. Special thanks go to the Australian Technology Network’s Industry Doctoral Training Centre (IDTC), which provided me with the opportunity to bridge an academic PhD with an industry placed research project, including its past directors Dr. Matt Brown and the UTS IDTC Node Leader Associate Prof. Yakov Zinder. I thank the IDTC industry partner CSIRO for partly funding this research, identifying the research problem, and supplying me with resources to carry out the research.

Finally, I would like to thank Dr. Sachi Purcal, Dr. Xiaolin Luo and A/Prof. Anthony Asher for discussions on material related to Chapters 3 and 4, Dr. Nicolas Langrené for discussion related to Chapter 5 and A/Prof. Juri Hinz for feedback on dynamic programming.
Abstract

In this thesis, we develop an expected utility model for retirement behaviour in the decumulation phase of Australian retirees with sequential family status subject to consumption, housing, investment, bequest, and a government-provided means-tested Age Pension. We account for mortality risk and risky investment assets, and we introduce a “health” proxy to capture the decreasing level of consumption for older retirees. The model is calibrated using the maximum likelihood method with empirical data on consumption and housing from the Australian Bureau of Statistic’s 2009-2010 ‘Household Expenditure Survey’ and ‘Survey of Income and Housing’. The calibrated model fits the characteristics of the data well to explain the behaviour of Australian retirees, and is then used to examine the optimal decisions given recent Age Pension policies and different family settings. Specifically, we examine optimal decisions for housing at retirement, and the optimal consumption and risky asset allocation depending on age and wealth for the Age Pension policies 2015-2017.

As the piecewise linearity in the Age Pension function requires the stochastic control problem to be solved numerically, we utilise the Least Squares Monte Carlo method to extend the problem with additional dimensions and control variables. This method is difficult to use with utility functions, as it can lead to a bad fit or bias from transforming variables. We suggest methods to account for this bias, and show that the Least Squares Monte Carlo is then accurate when applied to expected utility stochastic control problems. We then extend the optimal decisions to include annuitisation, as well as the option to scale housing in retirement or to access home equity through a reverse mortgage, and examine optimal decisions with respect to the Age Pension in retirement.
