September 2019

CERTIFICATION OF ORIGINAL AUTHORSHIP

I, Jiantao Li, declare that this thesis is submitted in fulfilment of the requirements for the award of Degree of PhD., in the Faculty of Engineering and Information Technology at the University of Technology Sydney.

This thesis is wholly my own work unless otherwise referenced or acknowledged. In addition, I certify that all information sources and literature used are indicated in the thesis.

This document has not been submitted for qualifications at any other academic institution.

This research is supported by the Australian Government Research Training Program.

Production Note:

Signature: Signature removed prior to publication.

Date: 31/01/2020

ACKNOWLEDGEMENTS

First and foremost, I would like to express my sincere gratitude to my principal supervisor, Prof. Xinqun Zhu, for his patience, insightful motivation and continuous support of my PhD study. Professor Zhu has offered much invaluable academic and personal advice to me. His immense knowledge and great personality have impressed and affected me greatly.

I also would like to thank my other supervisors, Prof. Bijan Samali, Prof. Jianchun Li and Prof. Siu-seong Law for their advice and guidance during my PhD study. Especially, Prof. Siu-seong Law's guidance helped me a lot in my research and paper writing. Without their help this thesis would not have been possible. I also wish to express my gratitude to Prof. Ying Lei and Dr. Lijun Liu of Xiamen University who have provided great help and guidance to me since long time ago. Their help has had a profound influence in my life.

The help from Mr. Robert Marshall in Western Sydney University for the arrangement and setting up the experimental testbed in the structural lab is much appreciated. I also very much appreciate the help from lab technicians Mr. Murray Bolden and Mr. Ali Ghari Zadeh during my experimental tests. The instrumentation system and data management on the actual cable-stay bridge are done by Data 61 and some experimental tests on the bridge were arranged by Dr. Makki Alamdari Mehrisadat. Their help is also greatly appreciated. I would also thank the staff in Centre for Infrastructure Engineering in Western Sydney University and School of Civil and Environmental Engineering in University of Technology Sydney who were always helpful and supportive when I needed help during my research.

Many thanks are given to my dear friends whom I am shared all those times with on the path to a PhD. I would like to express my gratitude towards the group of fellow students who have made the leisure time of the journey pleasant and enriched my daily life.

Last but not least, many thanks go to my family including my parents, my sister and my parents-in-law for their understanding and support. Special thanks is given to my wife, Dr. Siyi Lu, who is always by my side, encouraging me and trusting me. The love and smile from them make me strong, and this thesis is dedicated to them.

This research is supported by research funding of the Australian Research Council Discovery Project (DP160103197).

ABSTRACT

The inevitable deterioration and damage of bridge infrastructures due to repeated and excess traffic loading, environmental erosion and ageing are of great concern worldwide. Bridge structural health monitoring (SHM) is critical to obtain structural health information and early warning for potential damage. Most of the current SHM strategies measure vibration responses from sensors installed at different locations on the bridge. This direct approach poses several challenges, such as the high cost of the installation and maintenance of sensors, the need for extensive data processing and the insufficient spatial information. To seek a more economical and flexible way to monitor bridges, an indirect approach that measures responses of a passing vehicle has recently drawn great attention. This strategy involves the use of instrumented vehicles as a moving sensory system to capture bridge dynamic information via vehicle-bridge interaction (VBI). Sensors are installed on the vehicle axles or body. However, the responses from sensors on a moving vehicle are nonstationary, noisy and significantly affected by the surface roughness of the bridge. Therefore, most of the classical output-only system identification approaches based on the assumption of white noise excitation may fail to extract accurate structural dynamic properties.

This research aims to establish a framework for bridge SHM using vehicle-based mobile sensory systems. Indirect structural identification methods that consider the intrinsic nonstationary characteristics of VBI responses are proposed to extract the bridge dynamic parameters from vehicle acceleration responses. Firstly, a Short-time Stochastic Subspace Identification (STSSI) strategy was proposed to identify bridge modal frequencies and mode shapes. This method combines conventional SSI with a rescale procedure to estimate the bridge modal parameters using the responses of two instrumented vehicles.

Secondly, based on the sequential implementation of singular spectrum analysis (SSA) and blind source separation (BSS), a method named drive-by blind modal identification with singular spectrum analysis (SSA-BSS) was proposed to extract the response components from a single set of vehicle vibration responses. The bridge frequencies can be identified from the obtained bridge related components.

Numerical and experimental results clearly demonstrated the feasibility and effectiveness of the proposed methods for indirect identification of bridge modal frequencies and mode shapes. To gain insight on the time-dependent features of VBI system, a time-frequency (TF) analysis method called Synchroextracting transform (SET) was used to analyse the vehicle and bridge responses in TF domain. The instantaneous frequencies (IFs) of the system revealed the time-varying characteristics of the VBI system. Besides the indirect bridge modal identification, a two-step drive-by bridge damage detection strategy using vehicle axle responses was proposed. Dual Kalman filter (DKF) was applied to identify the interaction forces between vehicle and bridge. With the interaction forces, a sensitivity analysis was performed with regularization technique to identify the bridge damage. The proposed two-step damage detection method effectively identified the location and extent of the damages using vehicle axle responses, which demonstrated its great potential for drive-by bridge damage detection. Moreover, the SSA-BSS and the TF analysis strategy were successfully applied to analyse the responses from an in-situ VBI system.

In summary, an indirect bridge SHM technique using vehicle-based moving sensing system was developed in this study. Bridge modal identification and damage detection were conducted successfully using vehicle responses. Results further demonstrated that it can be a convenient and cost-effective alternative or a promising complement to conventional bridge SHM.
