# Inkjet printing of artificial latent fingermarks for improved quality assurance and research efficiency

---

A thesis submitted for the Degree of Doctor of Philosophy (Science)

***Romain STEINER***

*B.Sc, M.Sc*

***Centre for Forensic Science***

***University of Technology Sydney***

*February 2021*

---

## Certificate of original authorship

---

I, Romain Steiner declare that this thesis, is submitted in fulfilment of the requirements for the award of Doctor of Philosophy, in the Faculty of Science at the University of Technology Sydney.

This thesis is wholly my own work unless otherwise referenced or acknowledged. In addition, I certify that all information sources and literature used are indicated in the thesis.

This document has not been submitted for qualifications at any other academic institution.

This research is supported by an Australian Government Research Training Program.

Signature:      Production Note:  
                         Signature removed prior to publication.

Date: 16 February 2021

## Abstract

---

Research in fingerprint detection is a constantly evolving field where detection techniques are frequently improved or discovered to be able to detect as many fingerprints as possible in any given case. Quality control in fingerprint detection is paramount to ensuring detection techniques meet a scientifically accepted standard, but this control is hindered by the intrinsic variability of natural fingerprints. The chemical composition of fingerprint secretions, as well as deposition parameters such as the pressure applied or the amount of residue deposited on a substrate, can considerably vary between individuals and even for a same individual at different times. Because of this variability, it is challenging to unambiguously attribute any failure to detect fingerprints to the detection technique used rather than to a poor quality of the latent mark. The International Fingerprint Research Group (IFRG) guidelines aim at providing a standardised framework for researchers to reduce the effect of fingerprint variability. However, due to its unpredictable nature, this variability can never be completely controlled, and new detection techniques need to go through many different stages of experimentation (and peer-review) before being approved for use into standard operating procedures.

This thesis aimed at developing a method to reproducibly produce artificial fingerprints using an inkjet printer. Firstly, a standard solution mimicking real human secretions was developed and was shown to be reactive towards a range of commonly used detection techniques. Fingerprint patterns were then printed using an everyday inkjet printer by replacing the black ink with the synthetic secretions. Artificial fingerprints were printed on a porous and a non-porous substrate and were processed with some of the most used detection techniques on these kinds of surfaces. The artificial fingerprints were shown to be reactive towards most of the detection techniques tested. To validate the process, two different practical applications were examined: the production of proficiency tests for the assessment of laboratories methods and detection techniques, and an inter-laboratory comparison focussed on the physical developer technique. Both experiments showed very good potential for the use of artificial fingerprint for quality assessment and research.

The proposed method has potential to alleviate the effects of fingerprint variability by providing a way to reproducibly produced controllable fingerprints with a known and fixed

composition. Further research is imperative to improve the method but the results found showed that artificial fingermarks are the right way to go for a better research and quality assessment.

---

## Acknowledgements

---

Firstly, I would like to thank the University of Technology Sydney for the grant of this scholarship and this once-in-a-lifetime opportunity of undertaking a PhD at the other side of the world. The experiences these last three years have brought me are beyond any of my expectations and I cannot wait to see what the future holds for me.

A special acknowledgement goes to my supervisory panel, Dr Sebastien Moret and Prof. Claude Roux for their continual support from the very first day of this long journey, and Prof. Andy Bécue for his external view and precious expertise on the subject.

I also would like to thank the Ecole des Sciences Criminelles in Lausanne for allowing me to use their facilities for the 3 wonderful months I spent in Switzerland to work on my project and present my results to other PhD candidates from over 10 different countries.

I warmly address a special acknowledgement to the fingerprint donors who took some of their time (and I know it is precious!) to put their hands in latex gloves, rub their fingers on their forehead before pressing them against different substrates. This may not sound as a big deal, but this research would not have been the same without their availability.

I would like to give a special credit to all the UTS-WSU fingerprint research group for the fruitful discussions held during our regular meetings that helped me identifying issues during my project and ways to resolve them.

I acknowledge all the laboratories supervisors as well, especially Dr Linda Xiao and Dr Ronald Shimmon, for the inductions and different trainings which made my laboratory routine safer and enjoyable.

And last but not least, a very special “thank you” goes to my partner, Margarita, for her support in every possible way and for comforting me when I was feeling down and overwhelmed by this project. It felt great to have someone I love and who I can rely on and talk to after a hard day at work and you were always there for me, I love you.

## Overview

---

Research in fingerprint detection is a constantly evolving field where new detection techniques are frequently discovered, and existing ones are continuously improved in order to optimise the detection in any given case. Given the high number of laboratories developing and testing fingerprint detection techniques, research must be standardised in some way for the results to be comparable. The International Fingerprint Research Group (IFRG) Guidelines were published to set the framework in which fingerprint detection research has to be undertaken to guarantee valid results throughout the different phases of research and development in fingerprint research.

This need for standardisation arises from one specific characteristic of fingerprints: their inherent variability. Fingerprint variability is the result of two main parameters: the chemical composition of the secretions and the deposition factors. These two parameters have been studied and efforts have been reported to try to control fingerprint variability by developing standard solutions or by presenting methods to reproducibly deposit latent fingerprints. However, no real attempt at creating realistic artificial fingerprints, with a known chemical composition and a controllable deposition method, has been reported. Standard solutions are usually limited to simplistic mixtures that are reactive towards very few detection techniques. More complex solutions have been reported but their reactivity towards a large range of techniques has never been assessed. Moreover, a reproducible way to deposit fingerprint simulants has never been extensively studied nevertheless some promising results were obtained by using an inkjet printer.

This thesis aimed at developing a method to reproducibly produce artificial fingerprints with a known, controllable, and realistic composition using an inkjet printer. A simulant is considered as realistic if its reactivity towards an extended range of detection technique mimics real fingerprints. It should also allow for detection sequences to be assessed on different types of substrates. To achieve this goal, the research was divided into four main parts: (i) the evaluation of commercially available chemical pads to produce latent fingerprints, (ii) the development of artificial secretions, (iii) the presentation and optimisation of the inkjet printing method, and (iv) the demonstration of two different practical applications that could benefit from the use of artificial fingerprints.

The primary objective of the study in relation to the chemical pads was to evaluate their reliability to mimic real fingermarks when deposited on different substrates and processed with different detection techniques. The results obtained showed that, even if those pads can give a better control on the quality in some cases, they are too unreliable and cannot be recommended for use in research or practice. The deposition method using a rubber stamp was also shown to be unreproducible as it was impossible to precisely control the amount of simulant loaded on the stamps and deposited on the substrate. These results further highlighted the need for a more realistic simulant, combined with a better deposition method.

The second part of the thesis was dedicated to the choice of the most optimal synthetic solutions for the purpose of the research. Different synthetic sweat and sebum formulations found in the literature were tested and their reactivity towards common detection techniques was compared. Emulsions formed by mixing the sweat and sebum solutions were tested with the same detection techniques applied individually and in sequence, and the results confirmed the presence of both eccrine and sebaceous compounds within the emulsions. The choice was conclusively made to keep the formulations with the most optimal properties for inkjet printing.

The third, and fundamental part of the research, aimed at presenting and optimising the inkjet printing method to controllably print artificial fingermarks with the synthetic solutions developed. Two different printers were compared: a commercially available consumer inkjet printer (HP Printer), and a chemical printer (Fujifilm Printer). The high reproducibility of the HP Printer was first demonstrated by printing a consequent number of pages with the synthetic sweat solution. Artificial fingermarks were then printed with the different synthetic solutions (sweat, sebum, and emulsion) on a porous (paper) and a non-porous (acetate) substrate. The artificial fingermarks were processed with a range of detection techniques compatible with each of the substrates: 1,2-indanedione/zinc, ninhydrin, Oil Red O, and physical developer on paper; cyanoacrylate fuming, rhodamine 6G, gold/zinc vacuum metal deposition, and silver-black powder on acetate. The techniques were applied individually, as well as in sequence, and the results assessed. The best results were obtained on the fingermarks printed with the emulsion, which not only had a very similar quality and contrast compared to real fingermarks but could also be processed with detection

sequences on paper and acetate. Two main shortcomings were identified that were directly related to the use of the HP Printer: the impossibility to print on rigid or thick substrates and to print solutions that are too viscous. The Fujifilm Printer was used to try to overcome those issues, but the results showed that the printer suffered from an important lack of reproducibility and that the emulsion could not be printed without clogging the cartridge nozzles. Overall, inkjet printing was shown to be a very efficient, easy to apply, and a quick method to produce realistic artificial fingermarks. The quality of the results was highly reproducible and comparable to those obtained when real fingermarks were processed with the same detection techniques. For those reasons, the inkjet printing method could start being implemented by laboratories as positive control tests that would lead to an important gain of time and improved quality assurance in research and practice.

Finally, the last part of the research presented how the use of artificial fingermarks could be applied to the production of proficiency tests (PTs) and to inter-laboratory comparisons of detection techniques. PTs currently suffer from the intrinsic variability of fingermarks as two different forensic laboratories will never receive the exact same fingermark, thus making laboratory detection success comparisons challenging. A collaboration with Forensic Foundations (a PTs providing company) was undertaken where the fingermarks sent to the participants were printed with artificial secretions on a paper substrate. Pre-testing of the samples showed that all the fingermarks were properly printed and detected by correctly prepared working solutions of 1,2-indanedione/zinc and ninhydrin. It was demonstrated that the fingermarks sent to the participants were all consistent, which will conclusively contribute to a better review of their methods. The inter-laboratory study was undertaken in collaboration with the Ecole des Sciences Criminelles in Switzerland and focused on physical developer (PD) performance. Different patterns printed with the Fujifilm Printer were processed in Australia and Switzerland with two similar PD working solutions. However, because of the poor reproducibility of the Fujifilm Printer, no definitive conclusions could be drawn regarding any advantage in the efficiency of the PD technique applied in Switzerland or Australia. Despite these results, the potential of artificial fingermarks to compare different working solutions used by different laboratories remains very promising. Using reproducible printers such as the HP might resolve some of the shortcomings highlighted. Finally, artificial fingermarks have the potential to have an important impact in

the way research is undertaken. It is hoped that this thesis will lay the foundation of future developments to optimise the process even further.
