Abstract

Introduction

The concussion epidemic is a serious concern. Affected athletes may suffer debilitating neurological sequelae, impacting both their in-game performances and quality of life. Currently, a wide range of neurocognitive tests examining memory, balance and manifesting symptomology are used to aid a physician in the diagnosis of a concussion. However, considering up to 82% of those who suffer an episode experience some form of visual dysfunction, there is very little to no assessment of this on the sideline within Australian professional sport.

Methods

Four distinct studies were conducted to explore the role of eye movement dysfunction in concussion, using various visual instruments. The first three studies (Chapters 3 to 5) involved rugby union athletes from a semi-professional club in Sydney. Chapter 6 represents a retrospective study of medical records of children referred by physicians from across New South Wales and Australian Capital Territory to a tertiary outpatient paediatric sport and exercise hospital clinic in Sydney.

Results

Evaluation of a popular visual-based assessment device, the King-Devick test, indicated up to 30 attempts are required to obtain a ceiling effect. Analysis on 183 rugby athletes show a median improvement of 4.2 seconds from a player's first

attempt at the test to their overall best score. Considering only two attempts are currently recommended to constitute a baseline score, the data reveals that six to eight are needed for greater reliability.

Using digital eye-tracking techniques, experienced rugby athletes demonstrate superior eye movements compared to the normal population. Over 78% of players exhibited faster smooth pursuits, while over 73% produce more saccades. Previous history of concussion within the last 12 months demonstrate no impact on these conjugate eye movements.

Assessment of nine concussions in the acute phase using an orthoptic tool, the Royal Air Force (RAF) Rule, demonstrated 89% with reduced accommodative amplitudes and 33% with receded convergence. In a retrospective review of 142 medical records of paediatric patients with concussion, 28% had concussion-related visual dysfunction. These patients took a mean 24.5 days longer to recover from symptoms, compared to those without visual impairment. Females took a mean 21.3 days longer to recover than males, with 32% of all episodes related to rugby.

Conclusions

This PhD research has contributed knowledge regarding the importance of eye movement assessments within the concussion paradigm. Such tools demonstrate the ability to aid physicians with pre-injury baseline testing, post-injury diagnosis and a predictor of symptom recovery in athletic cohorts. The utility of these tools and areas for future development, have all been described.

*Referred to as convergence near point (CNP) in the ophthalmic literature. However, as papers have been published in sports medicine journals where near point of convergence (NPC) is commonly used, it will be referred as NPC throughout this thesis.

Overview of Thesis

This body of work, completed during my High Degree Research candidature, is presented in the format of thesis by compilation. In order to facilitate reading, the following overview provides an outline of my thesis's structure and brief description of each chapter. Chapter 3 has been published in the *Journal of Neurological Science* in 2020. The remaining results chapters (4 to 6) have been written in the format of articles prepared for submission. Finally, Chapter 7 provides an overall summary and conclusion to the thesis.

Chapter 1: Literature Review

The first thematic section of this thesis is a comprehensive review of the literature on concussion. It encompasses a wide range of studies identified through a search of databases, including Google Scholar, PubMed and Web of Science. Beginning with an overview of concussion as a global concern, the controversy surrounding the definition of concussion is then discussed, along with the worldwide and Australian prevalence of concussion and its pathophysiology.

The review then highlights the clinical features associated with concussion and summaries the current evidence on popular sideline diagnostic tools, before discussing the various causes of underreporting symptoms. It then focuses on the neurological impact following concussion, with a greater focus on two distinct conditions salient in the media, second impact syndrome and chronic traumatic encephalopathy.

Finally, the literature review covers the evidence for oculomotor dysfunction following concussion including describing the research of visual tools used for the detection of concussion, such as the King-Devick Test (KDT), Royal Air Force (RAF) Rule and Vestibular/Oculomotor Screening (VOMS) tool. Gaps within the literature surrounding these tools and areas for future research are addressed. A part of this chapter is an invited article with the candidate as first author, published in 2019 by the *Australian Journal of General Practice* (Appendix B).

Chapter 2: Methods

This chapter presents the methodological protocols for the subsequent studies conducted on the sporting sideline and in the field (Chapters 3 to 5) or hospital setting (Chapter 6). It discusses in detail sampling strategies and the sample size utilised, methods of data analysis and how each visual test was administered. It concludes with a brief discussion on the ethical considerations, as well as problems encountered during the project.

Chapter 3: The Learning Effect of the King-Devick Test

The next thematic section (Chapters 3 to 5) examines a number of visual tools in a cohort of rugby athletes in Sydney. Chapter 3 presents findings regarding the utility of the KDT during baseline testing. It observes the learning effect associated with repeated testing and aims to identify a point at which further repeated testing no longer improves the KDT score. There is discussion of the need for updating

standardised protocols recommended by the KDT manufacturers, to improve diagnostic procedures and patient care.

Chapter 4: Comparing the Smooth Pursuit and Saccadic Eye

Movements in Rugby Players to a Normative Database

Chapter 4 evaluates the RightEye Neurovision test, a digital eye-tracking device, on top division teams from a Sydney rugby club. Normative saccadic and smooth pursuit eye movement measures in these athletes are compared to a normative database provided by the RightEye company. Associations with concussion history and age were explored. Findings highlighted the need for individual pre-injury baseline testing in order to increase reliability in the detection of concussion using this device.

Chapter 5: Post-concussive Convergence and Accommodative

Dysfunction in Australian Rugby Union Athletes

In a cohort of semi-professional rugby athletes, Chapter 5 compares baseline visual functions (i.e. convergence and accommodation) to post-concussion measurements. It establishes any association with age, playing position, concussion history and previous history of double vision. This chapter aims to improve the concussion diagnostic battery with the addition of orthoptic testing on the sporting sideline.

Chapter 6: Concussion-Related Visual Dysfunction in Children: A

Retrospective Study

This final results chapter explores various predictors of recovery in children with concussion, aged between 5 and 18. It examines associations of concussion-related visual dysfunction with age, sex, symptoms and history of concussion primarily using the VOMS testing. The chapter addresses possible improvements to aspects of current paediatric concussion examination protocols used by physicians and looks to aid the development of strong and targeted recovery plans.

Chapter 7: Discussion and Conclusion

This chapter summarises the findings of this thesis and addresses areas for future research.

Statement of Original Authorship

CERTIFICATE OF ORIGINAL AUTHORSHIP

I Premkumar Gunasekaran declare that this thesis, is submitted in fulfilment of the requirements for the award of Doctor of Philosophy, in the Graduate School of Health at the University of Technology Sydney.

This thesis is wholly my own work unless otherwise referenced or acknowledged. In addition, I certify that all information sources and literature used are indicated in the thesis.

This document has not been submitted for qualifications at any other academic institution.

This research is supported by an Australian Government Research Training Program Scholarship and the Orthoptic Australia Research Grant.

Signature of Student:

Production Note:
Signature removed prior to publication.

Date: 18/01/2021

Acknowledgements

There are many people who have guided and supported me throughout some of the toughest years of my life. Without them, I would have never completed this project. These are just but a few.

Many thanks to McDonalds, KFC, Hungry Jacks and Guzman Y Gomez for supplying me with the adequate nutrients and energy to collect data and write this thesis.

On a serious note, I would like to firstly thank Dr. Vincent Nguyen, Dr. Amanda French and (soon-to-be Drs.) Michelle Courtney-Harris and Felicia Adinanto for their ongoing guidance. You are all amazing people who have always looked after me, even when you never had to.

I would also like to thank the rest of the faculty members in the Discipline of Orthoptics, at the University of Technology Sydney, for their ongoing support, encouragement and friendship. In particular my fellow PhD colleagues, Sahar and Mythili, who have been there since day one. I will treasure the numerous laughs, cries and international adventures we shared over the last few years.

To Sue, Donna, Julie and the rest of the team at Gordon Eye Surgery. I honestly, cannot thank you all enough for your ongoing support.

To my brilliant supervisor, Prof. Kathryn Rose, you are honestly the most intelligent person I have ever met. I will always be truly indebted to you for your time and energy. For this I am truly grateful and completely honoured that you believed in me. To Dr. Christopher Hodge, you are simply amazing. You were a leading light and I cannot thank you enough for the guidance and encouragement. To A/Prof. Clare Fraser, I cannot thank you enough for the amount you taught me in both the clinical and research settings. Although you were never officially my supervisor, this thesis could not have been completed without you. I definitely owe you many rounds of buffalo wings.

To my friends who have helped me along this journey, I thank you. You know who you all are. To my loving family, you all mean the world to me. Forever I am in debt to the time, support, patience, cooked meals, lifts, hugs and kisses you have given me.

And lastly this thesis is dedicated to my fiancé (now wife) and best friend, Dr. Rachel Yeong. Since the day we met, you have been my soulmate and one true love. Your support throughout the last few years has been second-to-none.
