<b>Abstract:</b>	<p>Accurate wind speed prediction has become increasingly important in wind power generation. However, the lack of efficient data preprocessing techniques and integration strategies has been a big obstacle to the development of wind power forecasting system. Therefore, a novel and advanced combined forecasting system comprising a data preprocessing, an integration strategy and several single models is designed in this study. The proposed model not only eliminates the impact of noise, but also integrates several single-model forecasting results through a weight optimization operator. In addition, the uncertain prediction of wind speed is also discussed in detail. The results show that: (a) The MAPE values of the proposed model are 2.8645%, 2.1843% and 2.8727% respectively for the point prediction. (b) The FICP values of the proposed model are 85.1697, 89.5410 and 88.0111 respectively at the significant level <math>\alpha = 0.05</math> for the uncertainty forecasting. The AWD values are 0.0559, 0.0400 and 0.0361 and the FINAW values are 0.0478, 0.0404 and 0.0390. It is reasonable to conclude that the proposed system can effectively boost the precision and stability of wind speed forecasting and provide a new approach for the exploitation of wind energy.</p>

**Declaration of interests**

The authors declare that they have no known competing financial interests or personal relationships that could have appeared to influence the work reported in this paper.

### Highlights

- A combined forecasting system including a data preprocessing, a combined and uncertainty prediction module is designed.
- An advanced data preprocessing technique is intended to remove the noise.
- A combined prediction strategy including optimal sub-model selection and weight optimization operators is proposed.
- The Pareto optimality of the solutions is theoretically proven.
- Interval prediction increases the accuracy and certainty of prediction results.

Dear Editors:

We would like to submit the enclosed manuscript entitled “**A novel combined forecasting model based on neural networks, deep learning approaches, and multi-objective optimization for short-term wind speed forecasting**” in **Energy**. No conflict of interest exists in the submission of this manuscript, and manuscript is approved by all authors for publication. I would like to declare on behalf of my co-authors that the work described was original research that has not been published previously, and not under consideration for publication elsewhere, in whole or in part. All the authors listed have approved the manuscript that is enclosed.

We deeply appreciate your consideration of our manuscript, and we look forward to receiving comments from the reviewers. If you have any queries, please don't hesitate to contact me at the address below.

Thank you and best regards.

Yours sincerely,

Yining An

**Dear editors and reviewers:**

Thank you very much for e-mailing us the comments raised by the respected reviewers. The manuscript **ID EGY-D-22-00224 “A novel combined forecasting model based on neural networks, deep learning approaches, and multi-objective optimization for short-term wind speed forecasting”** has been revised taking into account all of the helpful comments and suggestions. The details of the comments raised, the answers and the actions taken are presented here. All the changes made in the new revised manuscript have been marked **in yellow**. We appreciate for respected editors/reviewers’ warm work earnestly, and hope that the correction will meet with approval. We look forward to hearing from you.

Best regards,  
**Jianzhou Wang**

**Comment raised by respected Reviewer 1:**

**Comment 1:** In the Introduction section, it starts with 1.2. The heading of 1.1 is missing.

**Response:** Thank you very much for your valuable advice and it is helpful to improve the quality of our paper. We have corrected the error in the heading. Please see the revised manuscript **in section 1.1 in 3<sup>th</sup> page** for more details.

\*\*\*\*\*

**Comment 2:** In Section 2, the description of all algorithms should be given, rather than just that of denoising and optimization algorithm. This section should be re-written.

**Response:** Thank you for your suggestions. We have added the description of algorithms used in the study, with the additions shown below. Please see the revised manuscript **in section 2.2 in 7<sup>th</sup>-9<sup>th</sup> page** for more details. Thank you again for your valuable advice.

LSTM (long short-term memory) is a special type of RNNs. The key components of LSTM are memory cells and gates. The forget gate determines the number of the unit state  $C(t-1)$  remaining at current moment  $C(t)$  and is calculated as  $\overline{F}_{\sigma, \bar{b}, \bar{w}}(t) = \sigma(\bar{b}_f + \{x_t, h_{t-1}\} * \bar{w}_f)$ . The number of inputs  $x(t)$  stored in the cell state  $C(t)$  is determined in the calculation process of the input gate  $\overline{I}_{\sigma, \bar{b}, \bar{w}}(t) = \sigma(\bar{b}_i + \{x_t, h_{t-1}\} * \bar{w}_i)$ . Finally, the output gate controls the number of unit states  $C(t)$  to be output to the present output value  $h(t)$  and is given by  $\overline{O}_{\sigma, \bar{b}, \bar{w}}(t) = \sigma(\bar{w}_o * \{h_{t-1}, x_t\} + \bar{b}_o)$  where  $\bar{b}$  and  $\bar{w}$  are bias and weight, respectively. The calculation principle of GRU (gated recurrent unit) is very similar to LSTM. The difference is that GRU combines the forgetting gate and input gate in LSTM algorithm into update gate, so GRU consists of two gates, the update gate and the reset gate.

The hidden layer of CNN (convolutional neural network) consists of convolution  $C_L$ , pooling  $P_L$  and full connection  $F_L$ . The convolution process is represented as  $C_{x,y} = \sum_i^{p \times q} \bar{\omega}_i v_i$ , which is the sum of the product of the kernel weight and the brightness of the corresponding element in the input image. The main goal of pooling is to reduce the feature space of the maps. The fully connected layer is greatly important in combining the extracted features to obtain the output.

TCN (temporal convolutional networks) is suitable for sequence model construction under causal constraints, that is, the output  $\{\hat{y}_0, \hat{y}_1, \dots, \hat{y}_t\}$  can only be predicted based on the past observation  $\{x_0, x_1, \dots, x_t\}$ . Therefore, TCN can be designed as a nonlinear function with the mapping  $f : X^T \rightarrow Y^T$ . In addition, TCN also adds the dilated convolution and residual block to better extract historical information.

QRNN (quasi-recurrent neural networks) is the LSTM acceleration algorithm, including two components of convolution and pooling. In the convolution operation, the output of the input, forget and output gates can be expressed as  $Z = \tanh(W_z * X)$ ,  $F = \sigma(W_f * X)$  and  $O = \sigma(W_o * X)$ , where  $X$  is the input,  $W_z$ ,  $W_f$  and  $W_o$  are the convolution filters. There are three ways the pooling process can reduce the number of features, named f-pooling, fo-pooling and ifo-pooling based on the number of gates used.

ANFIS (adaptive neuro-fuzzy inference system) is a neural network based on fuzzy reasoning. The first layer is a fuzzy layer.  $\bar{O}_{i=1,2}^1 = \mu_{A_i}(x)$  and  $\bar{O}_{j=1,2}^1 = \mu_{B_j}(y)$  are output functions where  $x$  and  $y$  are the inputs with the respective membership functions  $\mu_{A_i}$  and  $\mu_{B_j}$ . The second layer calculates the weights of each membership function according to the previous outputs. The third layer normalizes the weights as  $\bar{O}_i^3 = \bar{w}_i = \bar{w}_i / (\bar{w}_1 + \bar{w}_2)$ . The fourth layer provides the output of the rule inference  $\bar{O}_i^4 = \bar{w}_i \bar{F}_i$ . The last layer generates the sum of each output  $\bar{O}_i^5 = \sum \bar{w}_i \bar{F}_i = (\sum \bar{w}_i \bar{F}_i) / \sum \bar{w}_i$ .

ELM (extreme learning machine) is a kind of feedforward neural network that includes input, hidden and output layers. The thresholds  $b$  and input weights  $\omega$  are randomly generated. The input and output are  $\bar{X} = (x_1^1, x_1^2, \dots, x_1^n) \in \mathbb{S}^n$  and  $\bar{T} = (t_1^1, t_1^2, \dots, t_1^m) \in \mathbb{S}^m$ . The hidden layer output is  $\bar{H}_{i=1, \dots, n}^{\omega, b}(x) = \bar{F}(x^T \bar{\omega}_i + b_i)$ , where  $\bar{F}(\bullet)$  is the activation function. The final output is  $\bar{O}_n^{\omega, b, \theta}(x) = \sum_{i=1}^n \bar{H}_i(x) \bar{\theta}(i)$ , where the output weights are  $\bar{\theta} = (\bar{\theta}_1, \dots, \bar{\theta}_n)$ .

BPNN (back propagation neural network) consists of input, hidden and output layers, and the calculation is:  $y_i = f_I \left( \mu_j + \sum_{m=t-n}^{t-1} \mu_{jm} y_m \right) (0 \leq \mu_j, \mu_{jm} \leq 1)$ ,  $y_t = f_0 \left( \lambda_0 + \sum_{j=1}^I \lambda_{0j} y_j \right) (0 \leq \lambda_0, \lambda_{0j} \leq 1)$ , where  $y_m$  and  $y_j$  are the inputs of the input and hidden layers,  $y_t$  is the predicted value at time  $t$ .  $N$  and  $I$  are the number of nodes in the input and the hidden layers. In the hidden and output layers,  $\mu_j$  and  $\lambda_0$  are the threshold values,  $\mu_{jm}$  and  $\lambda_{0j}$  are weights,  $f_I$  and  $f_0$  are activation functions.

On the basis of BPNN structure, ENN (elman neural network) adds a continuation layer to the hidden layer as a delay operator to achieve the purpose of memory. The

learning process is:  $\mathbf{x}(k) = f(w_1 x_c(k) + w_2(u(k-1)))$ ,  $\mathbf{y}(k) = g(w_3 \mathbf{x}(k))$ , where  $\mathbf{y}$  is the m-dimensional output vector,  $\mathbf{x}$  is the unit vector of n-dimensional middle layer,  $\mathbf{u}$  is the r-dimensional input vector,  $w_i (i = 1, 2, 3)$  is the connection weight of each layer,  $g(\bullet)$  and  $f(\bullet)$  are activation functions of output and middle layer neurons respectively.

GRNN (general regression neural network) is a kind of radial basis neural network, which is composed of input, pattern, summation and output layers.  $p_i = \exp[-(X - X_i)^T (X - X_i) / 2\sigma^2]$   $i = 1, 2, \dots, n$  is the neuron transfer function of the pattern layer, where  $X$  is the input variable and  $X_i$  is the learning sample of the  $i$ -th neuron. The output of neuron  $j$  can be calculated as  $y_j = S_{Nj} / S_D$ , where  $S_{Nj}$  and  $S_D$  are the arithmetic sum and weighted sum of neurons at the pattern layer.

### **Comment raised by respected Reviewer 3:**

**Comment 1:** Introduction: The reviewer suggested that the author add the following content: The reason why wind speed prediction technology can effectively improve the stability of wind power system.

**Response:** Thank you very much for your valuable advice and it is helpful to improve the quality of our paper. We have added the reason why wind speed prediction technology can effectively improve the stability of wind power system in the introduction section, and the corresponding modifications are listed as follows. Please see the revised manuscript **in section 1 in 3<sup>th</sup> page** for more details.

Owing to the rapid growth of the world economy, traditional energy sources such as natural gas and oil are being consumed in large quantities. Therefore, the development of sustainable green energy resources has received increasing attention [1]. Wind energy is a renewable energy resource with clean and effective characteristics that play an irreplaceable role in wind power generation. However, the instability and nonlinearity of wind speed limit the development of wind power and bring many obstacles to the wind power grid. Accurate wind speed prediction technology can

reduce the impact of wind speed characteristics, which not only helps power grid operators and decision makers to timely plan and dispatch the power system, but also reduces the failure risk of wind power system and improves power quality [2]. Hence, accurate wind speed prediction technology can effectively improve the stability of wind power generation system [3].

**Comment 2:** 1.2. Previous literature: First, I think the title number should be 1.1, not 1.2, and the same goes for 1.3. Then, it is suggested that the author divide the decomposition technique, prediction method and ensemble method into several paragraphs, so that scholars can read and understand them more clearly.

**Response:** Thank you for your suggestions. We have corrected the error in the heading, and we have also divided the content of section 1.1 into several paragraphs to make the reader read more clearly. Please see the revised manuscript in section 1.1 in 3<sup>th</sup> and 4<sup>th</sup> page for more details.

\*\*\*\*\*

**Comment 3:** 2. Design of the combined forecasting model: I think the following sentence is not very good: "The data denoising algorithm and multi-objective grey wolf optimization algorithm are presented in this part." The reviewer suggested that the authors change this part into a brief introduction of their proposed model.

**Response:** Thank you very much for your valuable advice and it is helpful to improve the quality of our paper. We have revised the introduction at the beginning of section 2. The corresponding modifications are as follows. Please see the revised manuscript in section 2 in 7<sup>th</sup> page for more details.

The proposed prediction model in this study is mainly composed of data preprocessing technology, multiple single models, multi-objective weight optimization operator and uncertainty prediction, which is used to improve the prediction accuracy and quantify the uncertainty of prediction results. The corresponding algorithm and theoretical introduction are presented in this part.

\*\*\*\*\*

**Comment 4:** 2.1 Data denoising strategy: Details of the authors' techniques and modeling to avoid data leaks can be added here.

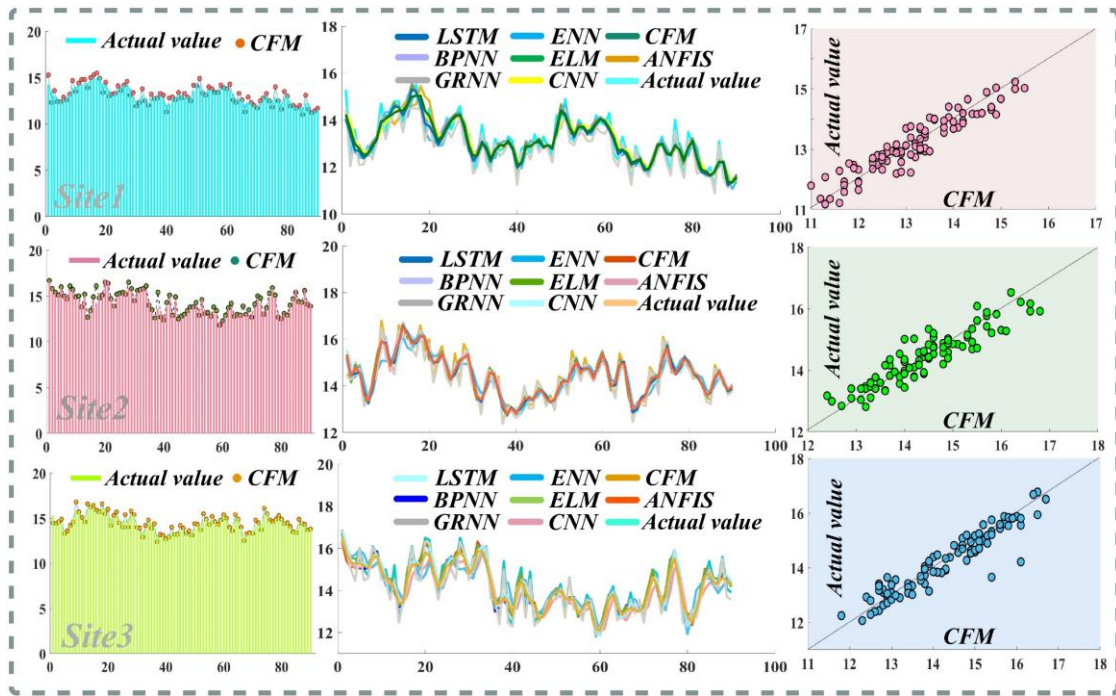

**Response:** Thank you for your suggestions. We have added details of the techniques and modeling to avoid data leakage in section 2.1. The corresponding modifications are as follows. Please see the revised manuscript **in section 2.1 in 7<sup>th</sup> page** for more details.

Before data denoising, we process the original data to prevent data leakage. Specifically, data leakage can cause the model to look accurate, but when applied to real life, the model can become very inaccurate, which is mainly divided into feature leakage and training data leakage. For feature leakage, features generally have a strong correlation with target variables. In this study, prevention of training data leakage is of greater concern to us. Before dividing the datasets, preprocessing the whole data set will lead to data leakage and make the information of the test set appear in the training set. Therefore, after dividing the datasets, we use decomposition technology for training set and test set respectively to prevent data leakage. The corresponding data denoising strategy is presented as follows.

## Abstract

Accurate wind speed prediction has become increasingly important in wind power generation. However, the lack of efficient data preprocessing techniques and integration strategies has been a big obstacle to the development of wind power forecasting system. Therefore, a novel and advanced combined forecasting system comprising a data preprocessing, an integration strategy and several single models is designed in this study. The proposed model not only eliminates the impact of noise, but also integrates several single-model forecasting results through a weight optimization operator. In addition, the uncertain prediction of wind speed is also discussed in detail. The results show that: (a) The MAPE values of the proposed model are 2.8645%, 2.1843% and 2.8727% respectively for the point prediction. (b) The FICP values of the proposed model are 85.1697, 89.5410 and 88.0111 respectively at the significant level  $\alpha = 0.05$  for the uncertainty forecasting. The AWD values are 0.0559, 0.0400 and 0.0361 and the FINAW values are 0.0478, 0.0404 and 0.0390. It is reasonable to conclude that the proposed system can effectively boost the precision and stability of wind speed forecasting and provide a new approach for the exploitation of wind energy.

**Keywords:** *Artificial intelligence; Data preprocessing; Combined forecasting model; Multi-objective optimization;*

# 1. Introduction

Owing to the rapid growth of the world economy, traditional energy sources such as natural gas and oil are being consumed in large quantities. Therefore, the development of sustainable green energy resources has received increasing attention [1]. Wind energy is a renewable energy resource with clean and effective characteristics that play an irreplaceable role in wind power generation. However, the instability and nonlinearity of wind speed limit the development of wind power and bring many obstacles to the wind power grid. Accurate wind speed prediction technology can reduce the impact of wind speed characteristics, which not only helps power grid operators and decision makers to timely plan and dispatch the power system, but also reduces the failure risk of wind power system and improves power quality [2]. Hence, accurate wind speed prediction technology can effectively improve the stability of wind power generation system [3].

## 1.1 Previous literature

At present, the wind speed forecasting approaches adopted in a large number of wind speed prediction studies include: (i) physical models, (ii) statistical models, (iii) Artificial intelligence models. Physical models are more suitable for long-term prediction, but have obvious defects for short-term prediction [4, 5]. Systematic errors can be easily generated in the predictions and the direction near the ground that result in differences in the predicted power generation when physical models are used [6, 7]. Dong et al. presented a hybrid model based on K-means cluster and general regression neural network (K-means-GRNN) of numerical weather forecasts; however, the practical application of the K-means-GRNN was difficult due to its high requirements on computation and information [8]. In contrast, statistical models have lower requirements for datasets [9]. Statistical models are usually linear models, such as the autoregressive moving average (ARMA) [10], the autoregressive integrated moving average model (ARIMA) [11, 12]. Movahed et al. predicted the development of cancer cells based on ARMA and Auto-Regressive (AR), and improved the forecasting accuracy [13]. However, for sequences with random and nonlinear characteristics, the statistical models were difficult to mine the information accurately and effectively [14].

Aiming at the deficiency of the above models, many researchers have performed in-depth studies on artificial intelligence (AI) prediction models [15, 16], which mainly include support vector machines (SVM) [17, 18], deep learning [19], and artificial neural networks (ANN) [20, 21]. AI prediction methods have strong generalization abilities, and fast calculation speeds, however, these single AI models may be affected by the initial parameters and are prone to fall into local optima during computations [22]. Considering the deficiency of the above approaches, combined models have been widely concerned, which often contain data preprocessing techniques and optimization algorithms [23].

On the one hand, because of the fluctuation and instability in wind speed, the use of data preprocessing techniques such as empirical mode decomposition (EMD) [24] and ensemble empirical mode decomposition (EEMD) [25] has been explored. In fact, disadvantages such as modes mix and boundary effect exist in EMD, although EEMD improves the shortcomings of EMD, it causes residual white noise [26]. Thus, an advanced strategy named improved complete ensemble empirical mode decomposition with adaptive noise (ICEEMDAN) is proposed in this study, which can add special white noise to obtain accurate modal values and improve model accuracy.

1 On the other traditional single models may not be able to balance accuracy and  
2 stability in prediction [27]. Wang et al. designed a hybrid model of wavelet neural  
3 network optimized by genetic algorithm (GA-WNN) based on variational mode  
4 decomposition (VMD) for wind speed forecasting, however, it remains to be explored  
5 that both accuracy and stability can be satisfied [28]. Based on this, this paper adopts  
6 the multi-objective grey wolf optimizer (MOGWO), which can combine multiple single  
7 models and optimize the assigned weight through to obtain stable and accurate results.  
8 Moreover, many studies ignore the reliability and uncertainty of wind speed prediction,  
9 which will cause potential risks in practical applications [29]. Thus, the uncertainty of  
10 wind speed prediction based on interval prediction has been discussed in this study.  
11 **Table 1** summarizes the common model types in the literature in recent years.  
12  
13

## 14 1.2 Contribution

16 Through the above analysis, a novel combined predictive framework is built based  
17 on neural networks, deep learning approaches, and multi-objective optimization to  
18 improve the forecasting accuracy. The developed system consists of four modules: a  
19 data preprocessing module, a combination prediction module, an uncertainty prediction  
20 module and an assessment module. Modal decomposition is adopted in the data  
21 preprocessing module decomposition of the original sequence to eliminate noise and  
22 obtain a smooth reconstructed sequence. The combination prediction module is  
23 designed to combine several single prediction models and optimize the assigned weight  
24 to obtain stable and accurate results, and interval prediction is used for quantifying  
25 uncertainty and improving model reliability. Nine metrics are proposed to evaluate the  
26 prediction performance in the last module. The contributions and innovations are  
27 summarized below:  
28  
29

30 (1) **A novel and advanced wind speed combined forecasting model (CFM) that**  
31 **includes data preprocessing and combined prediction and assessment is developed**  
32 **in this work.** Considering the uncertainty and fluctuation of the initial sequence, the  
33 prediction system given can overcome these shortcomings and achieve accurate and  
34 reliable prediction performance.  
35  
36

37 (2) **An advanced data preprocessing technique based on the decomposition**  
38 **and ensemble theory is intended to remove the noise in the initial sequence.** An  
39 advanced data preprocessing technique is chosen to reduce fluctuations and uncertainty  
40 to obtain a smooth sequence and improve the forecasting accuracy.  
41

42 (3) **A new combined prediction strategy that includes the selection of several**  
43 **sub-models to minimize the combination error and weight optimization operators**  
44 **is proposed.** Four sub-models are used to predict the original sequence, and their  
45 prediction results are integrated by the multi-objective grey wolf optimizer (MOGWO)  
46 to gain more precise and stable predictive effect.  
47

48 (4) **The Pareto optimality of the solutions from the combined system is**  
49 **theoretically proven.** The proof ensures that the optimal weight vector is obtained in  
50 the combined system through the leader selection mechanism and superior to those  
51 generated by the individual models, thus improving the prediction performance of the  
52 proposed system.  
53

54 (5) **An integrated and detailed assessment system was built to assess the point**  
55 **prediction (PP) and interval prediction (IP) results of CFM.** In the assessment  
56 module, nine metrics and several sites are used in the experiment with intervals of 10-  
57 min, 20-min and 30-min. In addition, the multi-step prediction and rolling input steps  
58 further are investigated to further ensure the accuracy and reliability of CFM.  
59

60 The overall structure of this paper is as follows. The approaches used in this study  
61  
62  
63  
64

Method	Published year	Contribution	Disadvantages
NWP-K means-GRNN [8]	2016	NWP and ANNs are combined and the parameters of clustering are discussed in detail.	high requirements on computation and information. Lack of comparison with other ANNs models.
ARMA-AR [13]	2021	The parameter values of AR and ARMA models are discussed.	Not suitable for non-linear data.
VMD-phase-space reconstruction (PSR) - BPNN, ELM, ENN-multi objective multi verse optimization (MOMVO) [15]	2021	A two-stage preprocessing way VMD-PSR is to analyze noise. MOMOVO is applied to combine BPNN, ELM and ENN.	The change of key parameter values needs to discuss.
ICEEMDAN- ARIMA, BPNN, ENN, GRNN, ELM-Modified MODA [23]	2020	The modes mix is solved in EMD and EEMD. Modified MODA enhances the optimization of weight coefficient.	The predictive power of selected single models is not fully demonstrated.
Flexible ensemble patch transformation (EPT)-CEEMDAN-CNN [26]	2022	EPT-CEEMDAN enhances the detection of local patterns embedded. Multiple deep learning models are compared.	Robustness and precision are not well balanced.
VMD-GA-WNN [28]	2017	VMD and GA are used to eliminate data noise and optimize WNN.	The optimization effect of single objective is limited.
CEEMDAN-ELM, RBF, GRNN, BPNN-MOGWO [29]	2021	MOGWO is adopted to integrate ELM, RBF, GRNN, BPNN.	Parameter setting of optimization algorithm is not explained.
ICEEMDAN-SVM- whale optimization algorithm (WOA) [30]	2017	WOA is used to optimize the parameters of SVM.	Fewer contrast models and optimization effect of single objective is limited.
VMD-BPNN, random vector functional link network (RVFL), ANFIS, GRNN-multi objective salp swarm algorithm (MSSA) and support vector regression (SVR) [31]	2021	Using the hybrid algorithm MSSA-SVR assigns coefficients to single models and the Pareto optimal solution of the optimization algorithm is analyzed.	Model parameter values are not displayed.
CEEMDAN-ELM, GRNN, ARIMA, BPNN, ENN- MOGOA[32]	2019	MOGOAO can optimize individual model weights.	Lack of discussion on parameter setting and comparison of other deep learning models.

## 2. Design of the combined forecasting model

The proposed prediction model in this study is mainly composed of data preprocessing technology, multiple single models, multi-objective weight optimization operator and uncertainty prediction, which is used to improve the prediction accuracy and quantify the uncertainty of prediction results. The corresponding algorithm and theoretical introduction are presented in this part.

### 2.1 Data denoising strategy

Before data denoising, we process the original data to prevent data leakage. Specifically, data leakage can cause the model to look accurate, but when applied to real life, the model can become very inaccurate, which is mainly divided into feature leakage and training data leakage. For feature leakage, features generally have a strong correlation with target variables. In this study, prevention of training data leakage is of greater concern to us. Before dividing the datasets, preprocessing the whole data set will lead to data leakage and make the information of the test set appear in the training set. Therefore, after dividing the datasets, we use decomposition technology for training set and test set respectively to prevent data leakage. The corresponding data denoising strategy is presented as follows.

The ICEEMDAN (ICE) is adopted to decompose the initial sequence, which is characterized by instability and fluctuation [30, 33]. ICE, which is based on CEEMDAN, can further reduce the noise and aliasing in IMF, which has a good decomposition ability. Suppose  $\tilde{\kappa}$  is the original sequence, and the operators  $\overline{\overline{D}}_j(\cdot)$ ,  $\overline{\overline{L}}(\cdot)$ , and  $\overline{\overline{\omega}}^{(i)}$  are introduced.  $\overline{\overline{D}}_j(\cdot)$  generates the  $j$ -th mode decomposed from the initial time series,  $\overline{\overline{L}}(\cdot)$  produces the local average of the original sequence  $\tilde{\kappa}$ , and  $\overline{\overline{\omega}}^{(i)}$  denotes white gaussian noise with  $\mu=0$  and unit variance  $\sigma^2$ . The specific processes in ICE are as follows:

The local mean of the  $i$ -th realizations  $\tilde{\kappa}^i(t) = \tilde{\kappa} + \chi_0 \cdot \overline{\overline{D}}_1(\overline{\overline{\omega}}^{(i)}(t))$  is first calculated to obtain the first residue  $R_1(t) : R_1(t) = \left\{ \overline{\overline{L}}(\tilde{\kappa}^i(t)) \right\}$ , where  $\chi_i$  is an operation item to remove noise and  $\{\bullet\}$  is the tool of the averaging process. The first mode can then be computed as  $IM_1 = \tilde{\kappa}(t) - R_1(t)$ .

The second residue  $R_2$  can be computed as  $R_1(t) + \chi_1 \overline{\overline{D}}_2(\overline{\overline{\omega}}^{(i)}(t))$ , and the second mode  $IM_2$  is obtained:

$$IM_2 = R_1(t) - R_2(t) = R_1(t) - \left\{ \overline{\overline{L}}(\chi_1 \overline{\overline{D}}_2(\overline{\overline{\omega}}^{(i)}(t)) + R_1(t)) \right\} \quad (1)$$

For  $j = 3, 4, \dots, n$ , the  $j$ -th residue is calculated as:

$$R_j(t) = \left\{ \overline{\overline{L}}(\chi_{j-1} \overline{\overline{D}}_j(\overline{\overline{\omega}}^{(i)}(t)) + R_{j-1}(t)) \right\} \quad (2)$$

$IM_j = R_{j-1}(t) - R_j(t)$  can also be obtained. After obtaining all the modes, the original sequenc  $\tilde{\kappa}$  can be reconstructed as  $\kappa' = \sum R_j(t) + \overline{\overline{R}}(t)$ , where  $\overline{\overline{R}}$  is the residual sequence.

### 2.2 Neural network models

LSTM (long short-term memory) is a special type of RNNs. The key components of LSTM are memory cells and gates. The forget gate determines the number of the

unit state  $C(t-1)$  remaining at current moment  $C(t)$  and is calculated as  $\overline{\overline{F}}_{\sigma, \bar{b}, \bar{w}}(t) = \sigma(\bar{b}_f + \{x_t, h_{t-1}\} * \bar{w}_f)$ . The number of inputs  $x(t)$  stored in the cell state  $C(t)$  is determined in the calculation process of the input gate  $\overline{\overline{I}}_{\sigma, \bar{b}, \bar{w}}(t) = \sigma(\bar{b}_i + \{x_t, h_{t-1}\} * \bar{w}_i)$ . Finally, the output gate controls the number of unit states  $C(t)$  to be output to the present output value  $h(t)$  and is given by  $\overline{\overline{O}}_{\sigma, \bar{b}, \bar{w}}(t) = \sigma(\bar{w}_o * \{h_{t-1}, x_t\} + \bar{b}_o)$  where  $\bar{b}$  and  $\bar{w}$  are bias and weight, respectively. The calculation principle of GRU (gated recurrent unit) is very similar to LSTM. The difference is that GRU combines the forgetting gate and input gate in LSTM algorithm into update gate, so GRU consists of two gates, the update gate and the reset gate.

The hidden layer of CNN (convolutional neural network) consists of convolution  $C_L$ , pooling  $P_L$  and full connection  $F_L$ . The convolution process is represented as  $C_{x,y} = \sum_i^{p*q} \bar{w}_i v_i$ , which is the sum of the product of the kernel weight and the brightness of the corresponding element in the input image. The main goal of pooling is to reduce the feature space of the maps. The fully connected layer is greatly important in combining the extracted features to obtain the output.

TCN (temporal convolutional networks) is suitable for sequence model construction under causal constraints, that is, the output  $\{\hat{y}_0, \hat{y}_1, \dots, \hat{y}_t\}$  can only be predicted based on the past observation  $\{x_0, x_1, \dots, x_t\}$ . Therefore, TCN can be designed as a nonlinear function with the mapping  $f: X^T \rightarrow Y^T$ . In addition, TCN also adds the dilated convolution and residual block to better extract historical information.

QRNN (quasi-recurrent neural networks) is the LSTM acceleration algorithm, including two components of convolution and pooling. In the convolution operation, the output of the input, forget and output gates can be expressed as  $Z = \tanh(W_z * X)$ ,  $F = \sigma(W_f * X)$  and  $O = \sigma(W_o * X)$ , where  $X$  is the input,  $W_z$ ,  $W_f$  and  $W_o$  are the convolution filters. There are three ways the pooling process can reduce the number of features, named f-pooling, fo-pooling and ifo-pooling based on the number of gates used.

ANFIS (adaptive neuro-fuzzy inference system) is a neural network based on fuzzy reasoning. The first layer is a fuzzy layer.  $\overline{\overline{O}}_{i=1,2}^1 = \mu_{A_i}(x)$  and  $\overline{\overline{O}}_{j=1,2}^1 = \mu_{B_j}(y)$  are output functions where  $x$  and  $y$  are the inputs with the respective membership functions  $\mu_{A_i}$  and  $\mu_{B_j}$ . The second layer calculates the weights of each membership function according to the previous outputs. The third layer normalizes the weights as  $\overline{\overline{O}}_i^3 = \bar{w}_i = \bar{w}_i / (\bar{w}_1 + \bar{w}_2)$ . The fourth layer provides the output of the rule inference  $\overline{\overline{O}}_i^4 = \bar{w}_i \bar{F}_i$ . The last layer generates the sum of each output  $\overline{\overline{O}}_i^5 = \sum \bar{w}_i \bar{F}_i = (\sum \bar{w}_i \bar{F}_i) / \sum \bar{w}_i$ .

ELM (extreme learning machine) is a kind of feedforward neural network that includes input, hidden and output layers. The thresholds  $b$  and input weights  $w$  are randomly generated. The input and output are  $\overline{\overline{X}} = (x_i^1, x_i^2, \dots, x_i^n) \in \mathbb{S}^n$  and  $\overline{\overline{T}} = (t_i^1, t_i^2, \dots, t_i^m) \in \mathbb{S}^m$ . The hidden layer output is  $\overline{\overline{H}}_{i=1, \dots, n}^{\omega, b, \theta}(x) = \overline{\overline{F}}(x^T \bar{w}_i + b_i)$ , where  $\overline{\overline{F}}(\bullet)$  is the activation function. The final output is  $\overline{\overline{O}}_n^{\omega, b, \theta}(x) = \sum_{i=1}^n \overline{\overline{H}}_i(x) \bar{\theta}(i)$ , where the output weights are  $\bar{\theta} = (\bar{\theta}_1, \dots, \bar{\theta}_n)$ .

BPNN (back propagation neural network) consists of input, hidden and output layers, and the calculation is:  $y_i = f_i \left( \mu_j + \sum_{m=t-n}^{t-1} \mu_{jm} y_m \right) (0 \leq \mu_j, \mu_{jm} \leq 1)$ ,  $y_t = f_0 \left( \lambda_0 + \sum_{j=1}^I \lambda_{0j} y_j \right) (0 \leq \lambda_0, \lambda_{0j} \leq 1)$ , where  $y_m$  and  $y_j$  are the inputs of the input and hidden layers,  $y_t$  is the predicted value at time  $t$ .  $N$  and  $I$  are the number of nodes in the input and the hidden layers. In the hidden and output layers,  $\mu_j$  and  $\lambda_0$  are the threshold values,  $\mu_{jm}$  and  $\lambda_{0j}$  are weights,  $f_i$  and  $f_0$  are activation functions.

On the basis of BPNN structure, ENN (elman neural network) adds a continuation layer to the hidden layer as a delay operator to achieve the purpose of memory. The learning process is:  $\mathbf{x}(k) = \mathbf{f}(w_1 x_c(k) + w_2(\mathbf{u}(k-1)))$ ,  $\mathbf{y}(k) = \mathbf{g}(w_3 \mathbf{x}(k))$ , where  $\mathbf{y}$  is the  $m$ -dimensional output vector,  $\mathbf{x}$  is the unit vector of  $n$ -dimensional middle layer,  $\mathbf{u}$  is the  $r$ -dimensional input vector,  $w_i (i=1,2,3)$  is the connection weight of each layer,  $\mathbf{g}(\cdot)$  and  $\mathbf{f}(\cdot)$  are activation functions of output and middle layer neurons respectively.

GRNN (general regression neural network) is a kind of radial basis neural network, which is composed of input, pattern, summation and output layers.  $p_i = \exp[-(X - X_i)^T (X - X_i) / 2\sigma^2]$   $i=1,2,\dots,n$  is the neuron transfer function of the pattern layer, where  $X$  is the input variable and  $X_i$  is the learning sample of the  $i$ -th neuron. The output of neuron  $j$  can be calculated as  $y_i = S_{Nj} / S_D$ , where  $S_{Nj}$  and  $S_D$  are the arithmetic sum and weighted sum of neurons at the pattern layer.

### 2.3 Multi objective grey wolf optimizer

Mirjalili et al. first proposed the MOGWO algorithm, who were inspired by social leadership and hunting technique of grey wolves [29, 34]. The alpha wolf  $\alpha_w$  is defined as the fittest solution, and the beta wolf  $\beta_w$  and delta wolf  $\delta_w$ , the second and third best solutions, respectively. The other candidate approaches are the omega wolves  $\omega_w$ .  $\alpha_w$ ,  $\beta_w$ , and  $\delta_w$  play a key role in capturing prey, and  $\omega_w$  follow  $\alpha_w$ ,  $\beta_w$ , and  $\delta_w$  to catch prey.

**Definition 1 Encircling process.** During the hunting of prey, the grey wolf location is updated as  $\overset{=i=\alpha,\beta,\delta}{L}_{wolf}(t+1) = \overset{=i}{L}_{prey}(t) - \mathbf{H} \otimes \overset{=i}{\Delta D}$ , where  $\overset{=i}{L}_{prey}(t)$  and  $\overset{=i=\alpha,\beta,\delta}{L}_{wolf}$  represent the location of prey and grey wolf, respectively, and  $\overset{=i=\alpha,\beta,\delta}{\Delta D} = \left| \mathbf{C} \otimes \overset{=i}{L}_{prey}(t) - \overset{=i}{L}_{wolf}(t) \right|$  is the distance between the grey wolf and its prey.  $\mathbf{C}$  and  $\mathbf{H}$  are coefficient vectors that are calculated as  $\mathbf{C} = 2 \otimes \gamma_2$  and  $\mathbf{H} = 2\zeta \otimes \gamma_1 - \zeta$ , respectively, where  $\zeta$  is the convergence factor, which decreases linearly from 2 to 0 with the number of iterations, and  $\Upsilon$  is a random vector  $\Upsilon = [\gamma_1, \gamma_2] \in [0,1]$ .

**Definition 2 Hunting behavior.** Suppose that  $\alpha_w$ ,  $\beta_w$  and  $\delta_w$  have a better command of the potential location of the prey and their distance from the prey is:

$\overset{=i=\alpha,\beta,\delta}{\Delta D} = \left| \mathbf{C}^i \otimes \overset{=i}{L}_{prey} - \overset{=i}{L}_{wolf} \right|$ . The current location of the wolves is then obtained as  $\overset{=i=\alpha,\beta,\delta}{L}_{wolf} = \overset{=i}{L}_{prey} - \mathbf{H}^i \otimes \overset{=i}{\Delta D}$ , and the location of  $\omega_w$  can be calculated as  $\overset{=\omega}{L}_{wolf} = \sum_{i=\alpha,\beta,\delta} \overset{=i}{L}_{wolf} / 3$ .

**Definition 3 Exploitation.** When  $H \in [-1,1]$  is random vector, the wolves can move at will between themselves and the prey. This narrows down the estimated location of the prey provided by  $\alpha_w$ ,  $\beta_w$  and  $\delta_w$ .

**Definition 4 Searching prey.** When  $|H| > 1$ , the wolf is forced to separate from its prey while  $|H| < 1$  helps to converge towards the prey. Moreover, the random vector  $C \in [0, 2]$  facilitates the discovery of new solutions.  $C > 1$  indicates that the location of the wolf has a great influence on the prey and  $C < 1$  indicates that the location of the wolf has little effect on the prey.

**Definition 5 Archive.** The archive is a store tool that saves or retrieves non-dominated Pareto optimal solutions.

**Definition 6 Leader selection mechanism.** This selection mechanism adopts the roulette wheel approach of  $P_i = c / N_i$  to choose the non-dominated pareto optimal solution where  $c$  is a fixed value and  $c > 1$ .  $N$  denotes the sum of Pareto optimal solutions obtained.

## 2.4 Multi objective problems (Mop)

In multi-objective problems, it is critical to find vector solutions. The concept of Pareto dominance is designed to facilitate the choice of the vector solutions. The Pareto optimal solution is defined as follows:

(1)  $\bar{\omega}^1$  is considered to dominate  $\bar{\omega}^2$ , i.e.,  $\bar{\omega}^1 \succ \bar{\omega}^2$ , if and only if  $\bar{\omega}^1$  and  $\bar{\omega}^2$  meet:  $[\forall p \in \{1, 2, \dots, t\}, \bar{F}_p(\bar{\omega}^1) \leq \bar{F}_p(\bar{\omega}^2)] \wedge [\exists q \in \{1, 2, \dots, t\}, \bar{F}_q(\bar{\omega}^1) < \bar{F}_q(\bar{\omega}^2)]$ , where  $\bar{F}$  is a function and  $t$  denotes a vector of numbers.

(2) The solution  $\bar{\omega}^1$  is called the Pareto optimal solution if the conditional equality  $\exists \bar{\omega}^i \in \mathbb{S}, \bar{\omega}^i \prec \bar{\omega}^1$  is satisfied, where  $\mathbb{S}$  denotes solution space.

(3) The Pareto optimal solution set  $\bar{P}^s$  includes all the Pareto optimal solutions and can be expressed as  $\bar{P}^s = \{\bar{\omega} \mid \exists \bar{\omega}^i \in \mathbb{S}, \bar{\omega} \succ \bar{\omega}^i\}$ .

To improve the precision and stability of the combined system, the MOGWO objective function is defined as:

$$\min \begin{cases} \bar{F}^1 = (1/Q) \sum_i^Q |(P^i - A^i) / A^i| \times 100\% \\ \bar{F}^2 = std(P^i - A^i) \quad i = 1, \dots, Q \end{cases} \quad (3)$$

where  $\bar{F}$  is the objective function,  $P$  and  $A$  represent the forecasted and true values.

## 2.5 The Pareto solution proof

The objectives in MOPs may often conflict with one another. The solutions in such problems can usually be expressed as the Pareto solution ( $\hat{\lambda}^*$ ). For MOPs, the Pareto solution ( $\hat{\lambda}^*$ ) that satisfies  $\exists \mathcal{G} \in \Omega_{s,t}, FIT(\hat{\lambda}^*) \prec FIT(\mathcal{G}^*)$  is adopted rather than the accurate solution. *Arc* is a tool for storing the non-dominated solutions ( $\hat{\lambda}'$ ); however, the storage capacity of *Arc* is limited and has the upper bound of  $\bar{Y}$ , that is,  $Y \prec \bar{Y}$ . Hence, in the process of updating *Arc*, it is necessary to compare the new solution  $\hat{\lambda}'$

and the present non-dominated solutions  $\{\hat{\lambda}_1^p, \hat{\lambda}_2^p, \dots, \hat{\lambda}_r^p\}$  in *Arc*. When  $\hat{\lambda}' \succ \hat{\lambda}_i^p$  or  $\hat{\lambda}' \sim \hat{\lambda}_i^p$ ,  $i \in [1, \mathcal{Y}]$ ,  $\hat{\lambda}'$  is added into *Arc* and  $\hat{\lambda}_i^p$  is removed or ranked behind  $\hat{\lambda}'$ . Once the *Arc* capacity has reached the upper bound  $\mathcal{Y} = \bar{\mathcal{Y}}$ , the most crowded segments will be removed with the deletion probability  $Pd_i = \mathcal{Y}_i / c$  ( $c > 1$ ). Then, the roulette-wheel technique is employed to compare the present solution with  $\hat{\lambda}'$  with the probability  $Pd_i = \mathcal{Y}_i / c$  ( $c > 1$ ) to determine the Pareto optimal solution  $\hat{\lambda}'$ . The pseudocode is listed as **Table 2**.

**Table 2** Pseudo code.

## 2.6 Uncertainty prediction

Interval prediction is proposed to quantify the uncertainty. According to maximum likelihood estimation (MLE), Weibull, Gamma, Rayleigh and Lognormal distribution are adopted to fit the data. Interval prediction results of CFM is testified and compared with basic models, the upper and lower bound is expressed as:

$Up^{i-th} = Fr^{i-th} + Dis_{1-\alpha/2} \cdot \sigma_{Dis}^* / \sqrt{n}$ ,  $Lo^{i-th} = Fr^{i-th} - Dis_{\alpha/2} \cdot \sigma_{Dis}^* / \sqrt{n}$ , where  $Dis_{1-\alpha/2}$  and  $Dis_{\alpha/2}$  are the critical values of optimal distribution and  $\alpha$  is the significance level ( $\alpha=0.05, 0.1$  and  $0.2$  in this study).

## 3. Flow of the combined forecasting system

In this study, a strategy of combining interval prediction with point prediction is adopted. A smooth sequence is first obtained using the ICE data preprocessing technique. Then, some single neural models are applied to forecast a stable sequence and obtain the forecasted values  $\bar{F} = (\hat{f}_1, \hat{f}_2, \hat{f}_3, \hat{f}_4)$ . In addition, the optimization operator is used to provide the most reasonable weights  $\bar{W} = (\omega_1, \omega_2, \omega_3, \omega_4)$  to combine the forecasted values in  $\bar{F}$ . Finally, confidence intervals of 80%, 90%, and 95% are set for the experiment. The main framework is illustrated in Fig.1.

## 3.1 Information of datasets

A wind power plant in Penglai (37°48'N 120°45'E), Shandong Province, China, is

used as the example. Seven sites are chosen to verify the performance of the proposed system, which include 10-min, 20-min and 30-min intervals. Besides, seven sites have the same sample size of 2220. The first 2000 samples are used for training, and the remaining 220 are used for testing. The details of the dataset are presented in **Table 3** and the features of the dataset are also visually depicted in **Fig. 2**.

**Table 3** Datasets.

**Fig.2** Wind speed data

### 3.2 Metrics

In the point prediction, six commonly used indicators are applied to evaluate model performance, namely **RMSE**, **MAE**, **MAPE**, **R<sup>2</sup>**, **IA** and **PE**, which can better reflect the prediction accuracy. The smaller the index values of **RMSE**, **MAE** and

**MAPE** are, the higher the prediction accuracy of the models are, while **R<sup>2</sup>** and **IA** are opposite. Three indicators named **FINAW**, **AWD**, and **FICP** are designed for interval forecasting. **FINAW** calculates the width of the interval. **AWD** is used to estimate the degree of deviation of the interval. **FICP** measures the extent to which ranges cover true values. The detailed information of metrics is presented in **Table 4**.

**Table 4** Metrics.

Metric	Expression	Definition
<b>RMSE</b>	$RMSE = \sqrt{(1/Q) \sum_{i=1}^Q (F_i - A_i)^2}$	Root mean square error
<b>MAE</b>	$MAE = (1/Q) \sum_{i=1}^Q  F_i - A_i $	Mean absolute error
<b>MAPE</b>	$MAPE = (1/Q) \sum_{i=1}^Q  (F_i - A_i) / A_i  \times 100\%$	Absolute percentage error mean
<b>R<sup>2</sup></b>	$R^2 = 1 - \frac{\sum_{i=1}^Q (F_i - A_i)^2}{\sum_{i=1}^Q (F_i - \bar{A})^2}$	Coefficient of determination
<b>IA</b>	$IA = 1 - \frac{\sum_{i=1}^Q (A_i - F_i)^2}{\sum_{i=1}^Q ( A_i - \bar{A}  +  \bar{A} - F_i )^2}$	Consistency of the predicted results
<b>PE</b>	$PE(i) = (F_i - A_i) / A_i \times 100\%$	The percentage of the predicted value in a specified error range
<b>FICP</b>	$FICP = \left( \sum_{i=1}^Q C_i / Q \right) \times 100\%$	Coverage probability of the forecast interval
<b>FINAW</b>	$FINAW = \sum_{i=1}^Q (U_i - L_i) / FR$	Normalized averaged width of the forecast interval
<b>AWD</b>	$AWD_i = \begin{cases} (A_i - U_i) / (U_i - L_i) & A_i > U_i \\ 0 & A_i \in [L_i, U_i] \\ (L_i - A_i) / (U_i - L_i) & A_i < L_i \end{cases}$ $AWD = \left( \sum_{i=1}^Q AWD_i \right) / FR$	<b>AWD<sub>i</sub></b> denotes the cumulative deviation of the forecast interval and <b>AWD</b> is the mean of cumulative deviation

**Note:**  $F_i$ ,  $A_i$  represents the forecasting and actual value of  $i$ -th. In the point prediction evaluation index,  $\pm 5\%$ ,  $\pm 10\%$  and  $\pm 15\%$  error range are chosen to calculate the index PE; In the interval prediction evaluation index, if  $A_i$  belongs  $[U_i, L_i]$ , then  $c_i=1$ , otherwise  $c_i=0$ ; FR means the range of predicted values.

### 3.3 Model parameter setting

The parameters for the neural network approaches are presented in **Table 5** and those for MOGWO and ICE in **Table 6**.

**Table 5** Parameters of single models.

Model	Symbol	Meaning	Value	Setting reasons
<b>BPNN</b>	$Tg$	Training goal	0.00004	Preset
	$Tf_{hid}$	Activation function of hidden	tansig	Preset
<b>ENN</b>	$E_{max}$	The maximum epochs	1000	Trial- error method
	$Tg$	Training goal	0.00004	Preset
<b>ELM</b>	$Tf$	Activation function of hidden	sig	Preset
<b>ANFIS</b>	$C_{ANf}$	The number of the cluster	10	Preset
	$E_{max}$	The maximum epochs	1500	Trial- error method
<b>GRNN</b>	$S_{GRnn}$	Spread	1	Preset
<b>LSTM</b>	$Lr$	Training learning rate	0.005	Preset
	$E_{max}$	The maximum epochs	2000	Trial- error method
<b>CNN</b>	$Lr$	Training learning rate	0.005	Preset
	$B_{min}$	MiniBatchsize	16	Trial- error method
<b>GRU</b>	$HL$	Numbers of hidden layers	40	Trial- error method

TCN	$E_{max}$	The maximum epochs	2000	Preset
	$H_L$	Numbers of hidden layers	50	Trial- error method
	$E_{max}$	The maximum epochs	500	Preset

**Table 6** Parameters of ICE and MOGWO.

Model	Symbol	Meaning	Value	Setting reasons
ICE	$Iter_{max}$	The maximum number of iterations	1000	Trial- error method
	$NR$	Realization Number	100	Trial- error method
	$Iter_{max}$	The maximum number of iterations	100	Trial- error method
	$As$	Archive size	100	Trial- error method
MOGWO	$P_s$	Population size	200	Trial- error method
	$\alpha$	Grid inflation	0.1	Preset
	$g$	Sum of grids per dimension	10	Preset
	$\beta$	Leader selection pressure	3	Preset

## 4. Experiment results

In this section, the results of the four comparative experiments and two validation tests to evaluate CFM are shown.

### 4.1 Selection of excellent sub models

Seven single predictive models named ANFIS [35, 36], LSTM [37, 38], CNN [39, 40], ELM [41-43], BPNN [44], GRNN [45, 46], and ENN [47] were chosen to forecast the original sequence in this study. To choose the most suitable models for improving the accuracy of CFM, the SEM strategy was developed [48]. The strategy is introduced below:

(1) The MAPE, MAE, and RMSE of every sub-model are calculated for one hundred iterations.

(2) Each index value is normalized as, for example,

$$\overline{MAE}_i = ((MAE_i - \min_{1 \leq i \leq Q}(MAE)) / (\max_{1 \leq i \leq Q}(MAE) - \min_{1 \leq i \leq Q}(MAE))) \quad (4)$$

(3) Weights are assigned to each index value and the SEM value is calculated as  $\overline{SEM}_i = (1/3) * \overline{MAE}_i + (1/3) * \overline{MAPE}_i + (1/3) * \overline{RMSE}_i$ .

The SEM values are listed in **Table 7**. A smaller SEM value indicates a higher model precision. Based on the results, ANFIS, LSTM, CNN, and ELM were chosen as the sub-models.

**Table 7** Results of SEM.

SEM	Model						
	GRNN	LSTM	ELM	BPNN	ANFIS	CNN	ENN
Site1_SEM	0.3300	0.3021	0.3797	0.2458	0.2871	0.2590	0.2589
Site2_SEM	0.2814	0.1587	0.2240	0.3657	0.3125	0.2200	0.4129
Site3_SEM	0.3251	0.4011	0.2134	0.2948	0.2250	0.3100	0.3201
SEM*	0.3122	<b>0.2873</b>	<b>0.2724</b>	0.3021	<b>0.2749</b>	<b>0.2630</b>	0.3306

**Note:** \* mean the average of SEM values of all sites.

### 4.2 Experiment I: Comparison between CFM and basic models

To demonstrate the performance of CFM, seven individual models were used for comparison in Experiment I. The results are as shown in **Table 8** and **Fig. 3**.

In **Table 8**, CFM exhibited the smallest error with MAPE, MAE and RMSE values of 2.8645%, 0.3217 and 0.4114 at site1. At site2, CFM exhibited the best performance with the MAPE value of 2.1843% compared to the other models, which had an average MAPE value of 4.8747%. The superior precision of CFM was thus verified. The IA and

$R^2$  can better reflect the agreement between the actual and the forecast data. At site1, CFM showed a better performance with the values of  $R^2$  and IA exceeding 97%, which was a 10% improvement in IA and  $R^2$  over the best model, GRNN.

Fig.3 Results of CFM and basic models

### 4.3 Experiment II: Comparison between CFM and single model based on ICE

Experiment II was designed to contrast the accuracy of CFM and other models based on ICE. The results are presented in Table 9 and Fig.4. The following conclusions can be drawn from the results:

It is obvious that CFM achieved the best prediction results at site1, with MAPE, MAE and RMSE values of 2.8645%, 0.3217, and 0.4114. For site2, the worst-performing model was ICE-ENN with MAPE exceeding 3.1044%. By contrast, the corresponding index value for CFM was 1% lower than that of ICE-ENN. For site3, CFM still exhibited the excellent performance with  $R^2$  exceeding 97%. The prediction error PE of CFM in the range of 5%, 10%, and 15% was greater than 80%, 90% and 95%, respectively. Obviously, CFM had more excellent prediction accuracy.

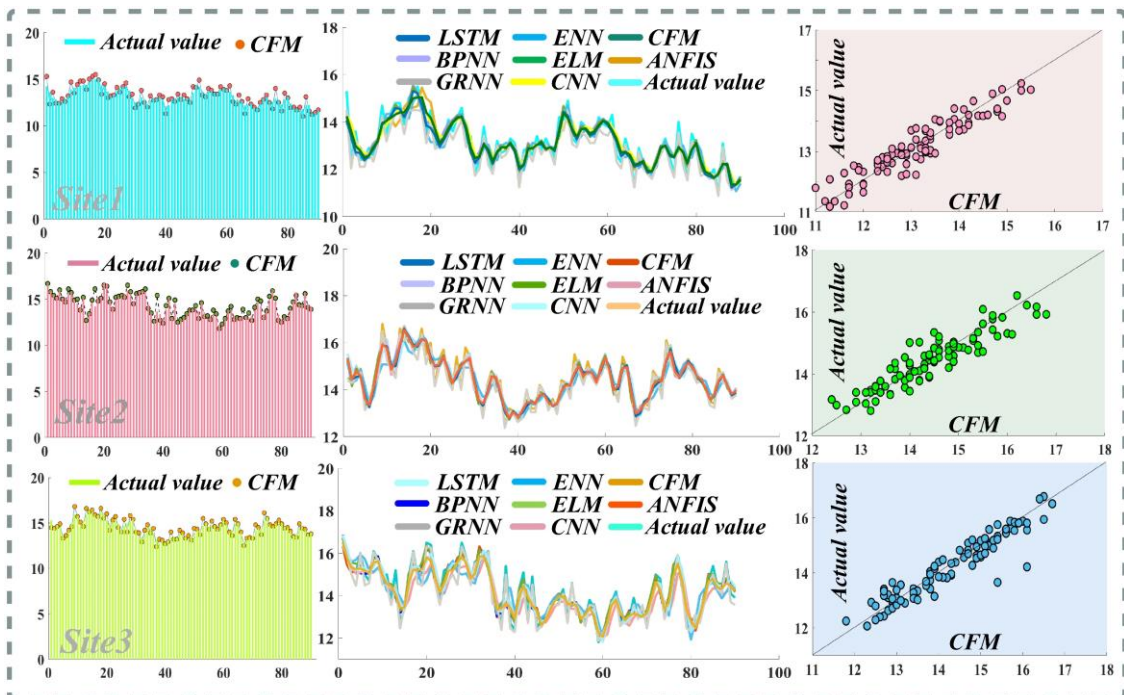

Fig.4 Results of CFM and denoising models

1  
2  
3 **4.4 Experiment III: Comparison between CFM and models with other denoising**  
4 **strategy**

5 In this section, three denoising strategies, namely, CEE, EMD, and EEMD, were  
6 chosen to verify the predictive abilities of CFM, and the detailed results are presented  
7 in **Table 10**. The following conclusions can be drawn:  
8

9 For site1, for the worst-performing EEMD-based model, the values of MAPE,  
10 MAE and RMSE were 4.6335%, 0.6592 and 0.6368, which far exceeded the  
11 corresponding values for CFM. For site2,  $MAPE_{EMD}=3.3387\%$  was obtained for the best  
12 classical model, which was based on EMD. In comparison, the smaller value of  
13  $MAPE_{CFM}=2.1843\%$  was obtained for CFM. Finally, for site3, the prediction errors of  
14 the comparison models in the range of 5% were almost less than 80%. It is not difficult  
15 to find that CFM performed better with  $PE_{CFM}^{5\%}$  exceeding 80%.  
16  
17  
18

19 **4.5 Experiment IV: Comparison between CFM and other optimization strategies**

20 In this part, three optimization strategies called MOGOA, MOALO and MODA  
21 were designed to evaluate the predictive precision of CFM. The calculation results are  
22 listed in **Table 11**. It can be easily seen that the CFM had excellent performance. For  
23 example, for site1, the  $MAPE_{CFM}=2.8645\%$  of CFM was 0.2%, 0.02% and 0.05% lower  
24 than those of MOGOA, MOALO, and MODA, respectively. In addition, only the  $R^2$  of  
25 CFM exceeded 95%, while its IA exceeded 97%. It can be found from the above  
26 evaluation index values that CFM has better performance in forecasting.

**Note:** The table lists the predicted results of CFM and basic models. The blacked part represents the evaluation index value of CFM. The equation of metrics are defined as:  $PE(i) = (F_i - A_i) / A_i \times 100\%$  ,  $MAE = (1/Q) \sum_{i=1}^Q |A_i - F_i|$  ,  $MAPE = (1/Q) \sum_{i=1}^Q |(A_i - F_i) / A_i| \times 100\%$  ,  $R^2 = -\sum_{i=1}^Q (A_i - F_i)^2 / \sum_{i=1}^Q (F_i - \bar{A})^2 + 1$  ,  $RMSE = ((1/Q) \sum_{i=1}^Q (A_i - F_i)^2)^{(1/2)}$  ,  $IA = -\sum_{i=1}^Q (A_i - F_i)^2 / \sum_{i=1}^Q (|A_i + \bar{A}| + |F_i - \bar{A}|)^2 + 1$  . In addition, GRU, TCN and QRNN are introduced in experiments I and II to make a more complete comparison.

## 4.6 Uncertainty forecasting

An interval estimate is based on a point estimate and can increase the prediction reliability and certainty [31]. In this subsection, four distributions were chosen to fit the sequence based on maximum likelihood estimation (MLE). They are Weibull, Gamma, Rayleigh and Lognormal distribution, which are shown in **Table 12**. After analysis, the Weibull distribution was adopted for the three sites, and the detailed parameter settings are presented in **Table 13**. Then, three indicators named FINAW, AWD, and FICP were designed for interval forecasting. The detailed results are depicted in **Fig.5** and **Table 14**.

The indicators were evaluated for the probabilities  $P_1=95\%$ ,  $P_2=90\%$ , and  $P_3=80\%$ . These probabilities can be expressed as  $(1-\alpha)\times 100\%$ . It is clear that the prediction accuracy at the significance level of  $\alpha=0.05$  was superior to the accuracies at  $\alpha=0.1$  and  $\alpha=0.2$ . At the significance level of  $\alpha=0.05$ , the FICP for CFM at every site exceeded 85%. In addition, at  $\alpha=0.1$ , the FICP for CFM was between 80% to 85%. The similar values of AWD and FINAW at different significance levels implies that most of the actual values fell within the predicted ranges and that CFM achieved excellent performance.

**Fig.5** The interval forecasting results

## 5. Discussion

In this section, the results of improvement ratio, hyperparametric analysis, and the exploration of input and multi-step forecasting, operation time, comparative analysis and practical applicability are discussed to further analyze the above experimental results.

### 5.1 Improvement ratio

The aim of the improvement indicator is to quantify the improvement in the predictive precision of CFM.  $IR_{MAPE}$ ,  $IR_{MAE}$  and  $IR_{RMSE}$  are designed to represent the improvement ratio. The details are shown in **Table 15**. For example, the models based on ICE for site1 had the values of  $IR_{MAPE}^{\text{ANFIS}}=9.2670\%$ ,  $IR_{MAPE}^{\text{LSTM}}=4.1438\%$ ,  $IR_{MAPE}^{\text{CNN}}=19.0262\%$ ,  $IR_{MAPE}^{\text{ELM}}=4.5895\%$ , which shows that the advantages of each model were

combined in CFM. For the different denoising methods, it is clear from the average value of 34% for  $\overline{\text{IR}}_{\text{MAPE}}^{\text{ave}}$  in these models that ICE played a key role in improving the forecasting accuracy. The various optimization strategies achieved an average value of 7.3309% for  $\overline{\text{IR}}_{\text{MAPE}}^{\text{ave}}$ . This implies that MOGWO could improve forecasting ability. There is no doubt that CFM was superior to the single models and the combined strategy achieved excellent prediction results.

## 5.2 Hyperparametric analysis

To investigate the influence of key parameter changes on the proposed model, only one key parameter was changed each time while the other parameters remained the same in this section. We changed the values of five parameters in the ICE and MOGWO algorithms. For ICE, the maximum iteration parameters values were [500, 3000] and the number realizations were [50, 100, 300]. For MOGWO, the archive size parameters values were [200,300,500], the maximum iteration parameter values were [50,150, 200], and the population sizes were [50,70,120]. The calculation results are shown in **Table 16**. With the change of parameter values, the precision of the model also changed. For example, at site1, the number realizations were set to 50,100 and 300. When 100 was selected, the proposed model achieved good MAPE values with 2.8645%, 2.1843% and 2.8727% in three sets. In general, it is not difficult to find that the parameter values selected in this paper perform better.

## 5.3 Influence of input step and multi-step prediction

This section adds sites 4-7 to better discuss the performance of the proposed model. Specifically, sites 4-5 use wind speed data at 20-minute intervals and sites 6-7 apply wind speed data at 30-minute intervals. The sample size and experimental mechanism are consistent with the above. Considering the neatness and symmetry of the table content, in sections 5.3.1 and 5.3.2, site1 (10-min), site2 (10-min), site4 (20-min), site5 (20-min), site6 (30-min) and site7 (30-min) are used to test the performance of the proposed model.

### 5.3.1 Influence of input step

To analyze the influence of different input steps on prediction more accurately, the input steps  $\lambda$  were adjusted to 3, 4 and 6, and a comparative test was performed to further explore the performance of the proposed forecasting system. From **Table 17**, it is easy to see that for the 10-min sites, when the input step  $\lambda$  was 3, the prediction errors of  $\text{MAPE}_{\lambda=3}^{\text{site1}} = 3.0833\%$  and  $\text{MAPE}_{\lambda=3}^{\text{site2}} = 2.4134\%$  were larger at those of other steps. For the 20-min sites,  $\text{PE}_{\lambda=3}^{5\%}$  and  $\text{PE}_{\lambda=4}^{5\%}$  are less than 70%, which implies that better forecasting results were obtained by CFM compared to  $\text{PE}_{\lambda=5}^{5\%} = 69.33\%$  at site4 and  $\text{PE}_{\lambda=5}^{5\%} = 72.22\%$  at site5. The prediction accuracy for the 30-min sites was obviously inferior to those of the previously mentioned sites; however, the input step 5 still performed well. From the above analysis, it can be concluded that as the time interval increased, the prediction accuracy decreased continuously, but the best performance was still obtained when the input step was 5.

### 5.3.2 Influence of multi-step prediction

The multistep forecasting ability of the proposed system is explored in the subsection. The details of the two-and three-step predictions are presented in **Table 18**.

For site1, which had 10-min intervals, the smallest errors of  $\text{MAPE}_{CFM}^{step2} = 4.4556\%$ ,  $\text{MAE}_{CFM}^{step2} = 0.5848$  were achieved by CFM compared to the other models, which had the average errors with MAPE and MAE values of 5.0829% and 0.7960 for two-step predictions. In addition, the accuracy of the three-step prediction was obviously lower than that of the two-step prediction, but the CFM still achieved the good result with  $R_{CFM}^2$  greater than 90%.

The accuracy decreased with longer interval times. For example, for the 20-min predictions by CFM, the MAPE values in two-step was 6.5225% at site4, which exceeded the values for the 10-min sites. For the 30-min predictions, the prediction error  $\text{MAPE}_{CFM}^{step2}$  increased to 9% at site6. These results indicate that the prediction system may be more suitable for short-term wind speed prediction.

#### 5.4 Operation time

Table 19 shows the mean operation time of all models used in this paper. It is clear that the proposed system had the longest calculation time, at 264.8361s. For basic models, the running time of BPNN was 0.4111, which was the least time in all models. The computation time of models based on ICE denoising algorithm was also short, which was 57.9170s, 19.2999s, 65.4855s, 36.4029s, 20.4532s, 18.9124s and 22.8657s. In addition, when applying other noise reduction algorithms or optimization algorithms, the time spent on combined models increased significantly, which was in the 100s to 200s range. Although the time consumed of the proposed model was longer than other models, it had superior predictive power. Its time was within the acceptable range and did not affect its practical application greatly.

**Table 19** Computing time.

Model	Computation time(s)	Model	Computation time(s)
CFM	264.8361	MOALO	197.8581

#### 5.5 Comparative analysis

Through the experiments above, the validity of the proposed model is proved. However, the results based only on the experimental mechanism in this paper may not be convincing. Therefore, in order to be fair, this section compares the proposed model with other similar studies. Specifically, Niu's model [32], Shao's model [29] and Liu's model [23] are used for comparative study. Niu et al. designed the combined model based on data preprocessing and optimization algorithm for wind speed forecasting, which obtained high accuracy with the smallest MAPE value of 2.89%. However, Niu et al. ignored the importance of uncertain predictions and the influence of parameters on model performance was not considered. Shao et al. used the same MOGWO algorithm and proposed a combined model based on decomposition-integration, but also lacked the exploration of uncertainty prediction and the influence of model

1 parameters. Liu et al. not only applied the improved optimization algorithm to point  
2 prediction and interval prediction of wind speed, but also considered the influence of  
3 different seasons on wind speed prediction. However, Liu's model lacked comparison  
4 with other literatures, and the results of parameter adjustment were not fully  
5 demonstrated. **Table 20** presents the comparison results of this study with other studies.

6 There is no unified comparison standard for model accuracy among different  
7 studies [49]. Therefore, to verify the accuracy of the proposed model, the evaluation  
8 index and datasets in this paper are applied in the models of Niu, Shao and Liu.  
9 Meanwhile, parameter settings are basically consistent with those in the original  
10 literature. Although the error between these models was not large, it was enough to  
11 show that the proposed model is superior to the models from comparative studies. For  
12 example, the MAPE value of the proposed model was 2.8645%, while Niu, Shao and  
13 Liu had values of 3.4181%, 4.0200% and 3.1835% respectively. The proposed model  
14 also had outstanding advantages in other indicators. Therefore, it can be reasonably  
15 concluded that the proposed model has excellent predictive ability.  
16  
17  
18  
19

## 20 **5.6 Practical applicability**

21 Efficient and timely wind speed prediction plays an important role in wind power  
22 generation system, which can not only meet people's demand for electricity, but also  
23 maximize economic benefits. Meanwhile, the proposed model in this paper can also be  
24 applied to other fields:

25  
26 **(a) Air quality forecasting.** Deep learning technology has been widely used in air  
27 monitoring, this proposed prediction system based on deep learning methods can be  
28 applied to the monitoring of air quality, for example, to timely predict air pollutant  
29 concentrations and to provide reasonable suggestions for travelling and improving the  
30 environment.  
31

32 **(b) Traffic forecasting.** In recent years, the prediction of traffic flow has become the  
33 focus of attention. This proposed system can sensitively capture the change of traffic  
34 flow, so as to reduce traffic congestion, relieve people's travel pressure and provide  
35 support for the development of intelligent transportation.  
36

37 **(c) Financial market forecasting.** This system can also be used in the prediction of  
38 future trends in stocks, funds, etc, timely providing technical support for discovery of  
39 potential financial risks.  
40  
41

## 42 **6. Conclusion and future work**

43 Wind energy has received increasing attention as a renewable energy source to  
44 address the shortages in the energy market. Nevertheless, the fluctuation and instability  
45 of wind speed still present difficulties for wind speed forecasting. An advanced wind  
46 speed prediction system was developed in this study. The ICE denoising strategy was  
47 first used to eliminate noise to obtain stationary sequences based on the de-composition  
48 and ensemble theory. Several single models were then adopted to predict the processed  
49 data. The optimal weights and final forecasting results were obtained using the  
50 MOGWO operator. The Pareto optimality of the MOGWO solutions was theoretically  
51 proven to ensure that the optimal weight vector can be obtained in the combined system.  
52 The point prediction results show that the MAPE values of the proposed model were  
53 2.8645%, 2.1843% and 2.8727% respectively. Besides, for uncertainty forecasting, the  
54 FICP values of the proposed model were 85.1697, 89.5410 and 88.0111 respectively at  
55 the significant level  $\alpha = 0.05$ . The AWD values were 0.0559, 0.0400 and 0.0361 and  
56 the FINAW values were 0.0478, 0.0404 and 0.0390. It is clear that the proposed system  
57  
58  
59  
60  
61  
62  
63  
64  
65

exhibits remarkable accuracy and stability performance. This system can hence provide accurate and real-time wind power information and contribute to wind power generation.

There are still some areas that need to be improved in future studies, for example: (1) In order to further improve the prediction accuracy, the influence of temperature, wind direction and other variables on wind speed prediction needs to be further discussed. (2) More advanced deep learning algorithms can be applied to future research to improve the accuracy of developed system. (3) Using more efficient preprocessing methods deals with unstable, random wind speed data. In addition, the effects of different preprocessing methods need to be further explored.

	90%	83.8456	0.0646	0.0364	84.6134	0.0519	0.0339	81.1961	0.0641	0.0327
	80%	80.3296	0.0796	0.0305	81.0431	0.0659	0.0264	78.2684	0.0965	0.0255

**Note:** This table lists the interval forecasting results of CFM, which can further show the accuracy of CFM. The formula of **FICP**, **FINAW** and **AWD** are:  $\text{FICP} = \left( \sum_{i=1}^o C_i / M \right) \times 100\%$ ,  $\text{FINAW} = \sum_{i=1}^o (U_i - L_i) / FR$ , if  $A_i > U_i$ , then  $\text{AWD}_i = (A_i - U_i) / (U_i - L_i)$ , if  $A_i \in [L_i, U_i]$ , then  $\text{AWD}_i = 0$ , if  $A_i < L_i$ , then  $\text{AWD}_i = (L_i - A_i) / (U_i - L_i)$ . Thus,  $\text{AWD} = \left( \sum_{i=1}^o \text{AWD}_i \right) / FR$ ,  $FR$  represents the range of predicted values.

**Table 20** Comparison results.

Authors	Published year	Algorithm	Results	Similarity	Difference				
Niu et al. [32]	2019	1. CEEMDAN 2. BPNN+GRNN+ENN+ELM +ARIMA 3. MOGOA	The combined model obtained high accuracy, the MAPE values of five data sets are 3.14%, 2.89%, 3.43%, 4.06% and 3.62% respectively.	Preprocessing methods, several single models and optimization algorithms are used. Different denoising strategies and optimization methods are compared.	Uncertain predictions and the influence of parameters on model performance are not discussed. The operation time of models is ignored.				
Shao et al. [29]	2021	1. CEEMDAN 2. BPNN+GRNN+RBF+ ELM 3. MOGWO	Several experiments verify the effectiveness of the proposed model with the smallest MAPE value of 2.03%.	The same optimization algorithm is used. Different denoising strategies and optimization methods are compared.	Uncertain predictions and the influence of model parameters are not discussed. The operation time of models is ignored. Lack comparison with other literatures.				
Liu et al. [23]	2019	1. ICEEMDAN 2. BPNN+GRNN+ENN+ELM +ARIMA 3. MMODA	The proposed model can improve the prediction accuracy. MAPE values of multi-step prediction are 3.15%, 4.41% and 5.02% respectively.	The same denoising strategy is applied. Multiple single models are applied. Different denoising strategies and optimization methods are compared.	The optimization algorithm is improved. Wind speed forecasts for different seasons are discussed. The result of parameter adjustment is not discussed in detail.

## Abstract

Accurate wind speed prediction has become increasingly important in wind power generation. However, the lack of efficient data preprocessing techniques and integration strategies has been a big obstacle to the development of wind power forecasting system. Therefore, a novel and advanced combined forecasting system comprising a data preprocessing, an integration strategy and several single models is designed in this study. The proposed model not only eliminates the impact of noise, but also integrates several single-model forecasting results through a weight optimization operator. In addition, the uncertain prediction of wind speed is also discussed in detail. The results show that: (a) The MAPE values of the proposed model are 2.8645%, 2.1843% and 2.8727% respectively for the point prediction. (b) The FICP values of the proposed model are 85.1697, 89.5410 and 88.0111 respectively at the significant level  $\alpha = 0.05$  for the uncertainty forecasting. The AWD values are 0.0559, 0.0400 and 0.0361 and the FINAW values are 0.0478, 0.0404 and 0.0390. It is reasonable to conclude that the proposed system can effectively boost the precision and stability of wind speed forecasting and provide a new approach for the exploitation of wind energy.

**Keywords:** *Artificial intelligence; Data preprocessing; Combined forecasting model; Multi-objective optimization;*

## 1. Introduction

Owing to the rapid growth of the world economy, traditional energy sources such as natural gas and oil are being consumed in large quantities. Therefore, the development of sustainable green energy resources has received increasing attention [1]. Wind energy is a renewable energy resource with clean and effective characteristics that play an irreplaceable role in wind power generation. However, the instability and nonlinearity of wind speed limit the development of wind power and bring many obstacles to the wind power grid. Accurate wind speed prediction technology can reduce the impact of wind speed characteristics, which not only helps power grid operators and decision makers to timely plan and dispatch the power system, but also reduces the failure risk of wind power system and improves power quality [2]. Hence, accurate wind speed prediction technology can effectively improve the stability of wind power generation system [3].

### 1.1 Previous literature

At present, the wind speed forecasting approaches adopted in a large number of wind speed prediction studies include: (i) physical models, (ii) statistical models, (iii) Artificial intelligence models. Physical models are more suitable for long-term prediction, but have obvious defects for short-term prediction [4, 5]. Systematic errors can be easily generated in the predictions and the direction near the ground that result in differences in the predicted power generation when physical models are used [6, 7]. Dong et al. presented a hybrid model based on K-means cluster and general regression neural network (K-means-GRNN) of numerical weather forecasts; however, the practical application of the K-means-GRNN was difficult due to its high requirements on computation and information [8]. In contrast, statistical models have lower requirements for datasets [9]. Statistical models are usually linear models, such as the autoregressive moving average (ARMA) [10], the autoregressive integrated moving average model (ARIMA) [11, 12]. Movahed et al. predicted the development of cancer cells based on ARMA and Auto-Regressive (AR), and improved the forecasting accuracy [13]. However, for sequences with random and nonlinear characteristics, the statistical models were difficult to mine the information accurately and effectively [14].

Aiming at the deficiency of the above models, many researchers have performed in-depth studies on artificial intelligence (AI) prediction models [15, 16], which mainly include support vector machines (SVM) [17, 18], deep learning [19], and artificial neural networks (ANN) [20, 21]. AI prediction methods have strong generalization abilities, and fast calculation speeds, however, these single AI models may be affected by the initial parameters and are prone to fall into local optima during computations [22]. Considering the deficiency of the above approaches, combined models have been widely concerned, which often contain data preprocessing techniques and optimization algorithms [23].

On the one hand, because of the fluctuation and instability in wind speed, the use of data preprocessing techniques such as empirical mode decomposition (EMD) [24] and ensemble empirical mode decomposition (EEMD) [25] has been explored. In fact, disadvantages such as modes mix and boundary effect exist in EMD, although EEMD improves the shortcomings of EMD, it causes residual white noise [26]. Thus, an advanced strategy named improved complete ensemble empirical mode decomposition with adaptive noise (ICEEMDAN) is proposed in this study, which can add special white noise to obtain accurate modal values and improve model accuracy.

1 On the other traditional single models may not be able to balance accuracy and  
2 stability in prediction [27]. Wang et al. designed a hybrid model of wavelet neural  
3 network optimized by genetic algorithm (GA-WNN) based on variational mode  
4 decomposition (VMD) for wind speed forecasting, however, it remains to be explored  
5 that both accuracy and stability can be satisfied [28]. Based on this, this paper adopts  
6 the multi-objective grey wolf optimizer (MOGWO), which can combine multiple single  
7 models and optimize the assigned weight through to obtain stable and accurate results.  
8 Moreover, many studies ignore the reliability and uncertainty of wind speed prediction,  
9 which will cause potential risks in practical applications [29]. Thus, the uncertainty of  
10 wind speed prediction based on interval prediction has been discussed in this study.  
11 **Table 1** summarizes the common model types in the literature in recent years.  
12

## 13 **1.2 Contribution**

14 Through the above analysis, a novel combined predictive framework is built based  
15 on neural networks, deep learning approaches, and multi-objective optimization to  
16 improve the forecasting accuracy. The developed system consists of four modules: a  
17 data preprocessing module, a combination prediction module, an uncertainty prediction  
18 module and an assessment module. Modal decomposition is adopted in the data  
19 preprocessing module decomposition of the original sequence to eliminate noise and  
20 obtain a smooth reconstructed sequence. The combination prediction module is  
21 designed to combine several single prediction models and optimize the assigned weight  
22 to obtain stable and accurate results, and interval prediction is used for quantifying  
23 uncertainty and improving model reliability. Nine metrics are proposed to evaluate the  
24 prediction performance in the last module. The contributions and innovations are  
25 summarized below:  
26

27 (1) **A novel and advanced wind speed combined forecasting model (CFM) that**  
28 **includes data preprocessing and combined prediction and assessment is developed**  
29 **in this work.** Considering the uncertainty and fluctuation of the initial sequence, the  
30 prediction system given can overcome these shortcomings and achieve accurate and  
31 reliable prediction performance.  
32

33 (2) **An advanced data preprocessing technique based on the decomposition**  
34 **and ensemble theory is intended to remove the noise in the initial sequence.** An  
35 advanced data preprocessing technique is chosen to reduce fluctuations and uncertainty  
36 to obtain a smooth sequence and improve the forecasting accuracy.  
37

38 (3) **A new combined prediction strategy that includes the selection of several**  
39 **sub-models to minimize the combination error and weight optimization operators**  
40 **is proposed.** Four sub-models are used to predict the original sequence, and their  
41 prediction results are integrated by the multi-objective grey wolf optimizer (MOGWO)  
42 to gain more precise and stable predictive effect.  
43

44 (4) **The Pareto optimality of the solutions from the combined system is**  
45 **theoretically proven.** The proof ensures that the optimal weight vector is obtained in  
46 the combined system through the leader selection mechanism and superior to those  
47 generated by the individual models, thus improving the prediction performance of the  
48 proposed system.  
49

50 (5) **An integrated and detailed assessment system was built to assess the point**  
51 **prediction (PP) and interval prediction (IP) results of CFM.** In the assessment  
52 module, nine metrics and several sites are used in the experiment with intervals of 10-  
53 min, 20-min and 30-min. In addition, the multi-step prediction and rolling input steps  
54 further are investigated to further ensure the accuracy and reliability of CFM.

**Table 1** Various studies on wind speed.

Method	Published year	Contribution	Disadvantages
NWP-K means-GRNN [8]	2016	NWP and ANNs are combined and the parameters of clustering are discussed in detail.	high requirements on computation and information. Lack of comparison with other ANNs models.
ARMA-AR [13]	2021	The parameter values of AR and ARMA models are discussed.	Not suitable for non-linear data.
VMD-phase-space reconstruction (PSR) - BPNN, ELM, ENN-multi objective multi verse optimization (MOMVO) [15]	2021	A two-stage preprocessing way VMD-PSR is to analyze noise. MOMOVO is applied to combine BPNN, ELM and ENN.	The change of key parameter values needs to discuss.
ICEEMDAN- ARIMA, BPNN, ENN, GRNN, ELM-Modified MODA [23]	2020	The modes mix is solved in EMD and EEMD. Modified MODA enhances the optimization of weight coefficient.	The predictive power of selected single models is not fully demonstrated.
Flexible ensemble patch transformation (EPT)-CEEMDAN-CNN [26]	2022	EPT-CEEMDAN enhances the detection of local patterns embedded. Multiple deep learning models are compared.	Robustness and precision are not well balanced.
VMD-GA-WNN [28]	2017	VMD and GA are used to eliminate data noise and optimize WNN.	The optimization effect of single objective is limited.
CEEMDAN-ELM, RBF, GRNN, BPNN-MOGWO [29]	2021	MOGWO is adopted to integrate ELM, RBF, GRNN, BPNN.	Parameter setting of optimization algorithm is not explained.
ICEEMDAN-SVM- whale optimization algorithm (WOA) [30]	2017	WOA is used to optimize the parameters of SVM.	Fewer contrast models and optimization effect of single objective is limited.
VMD-BPNN, random vector functional link network (RVFL), ANFIS, GRNN-multi objective salp swarm algorithm (MSSA) and support vector regression (SVR) [31]	2021	Using the hybrid algorithm MSSA-SVR assigns coefficients to single models and the Pareto optimal solution of the optimization algorithm is analyzed.	Model parameter values are not displayed.
CEEMDAN-ELM, GRNN, ARIMA, BPNN, ENN- MOGOA[32]	2019	MOGOAO can optimize individual model weights.	Lack of discussion on parameter setting and comparison of other deep learning models.

## 2. Design of the combined forecasting model

The proposed prediction model in this study is mainly composed of data preprocessing technology, multiple single models, multi-objective weight optimization operator and uncertainty prediction, which is used to improve the prediction accuracy and quantify the uncertainty of prediction results. The corresponding algorithm and theoretical introduction are presented in this part.

### 2.1 Data denoising strategy

Before data denoising, we process the original data to prevent data leakage. Specifically, data leakage can cause the model to look accurate, but when applied to real life, the model can become very inaccurate, which is mainly divided into feature leakage and training data leakage. For feature leakage, features generally have a strong correlation with target variables. In this study, prevention of training data leakage is of greater concern to us. Before dividing the datasets, preprocessing the whole data set will lead to data leakage and make the information of the test set appear in the training set. Therefore, after dividing the datasets, we use decomposition technology for training set and test set respectively to prevent data leakage. The corresponding data denoising strategy is presented as follows.

The ICEEMDAN (ICE) is adopted to decompose the initial sequence, which is characterized by instability and fluctuation [30, 33]. ICE, which is based on CEEMDAN, can further reduce the noise and aliasing in IMF, which has a good decomposition ability. Suppose  $\tilde{\kappa}$  is the original sequence, and the operators  $\overline{\overline{D}}_j(\cdot)$ ,  $\overline{\overline{L}}(\cdot)$ , and  $\overline{\overline{\omega}}^{(i)}$  are introduced.  $\overline{\overline{D}}_j(\cdot)$  generates the  $j$ -th mode decomposed from the initial time series,  $\overline{\overline{L}}(\cdot)$  produces the local average of the original sequence  $\tilde{\kappa}$ , and  $\overline{\overline{\omega}}^{(i)}$  denotes white gaussian noise with  $\mu=0$  and unit variance  $\sigma^2$ . The specific processes in ICE are as follows:

The local mean of the  $i$ -th realizations  $\tilde{\kappa}^i(t) = \tilde{\kappa} + \chi_0 \cdot \overline{\overline{D}}_1(\overline{\overline{\omega}}^{(i)}(t))$  is first calculated to obtain the first residue  $R_1(t) : R_1(t) = \left\{ \overline{\overline{L}}(\tilde{\kappa}^i(t)) \right\}$ , where  $\chi_i$  is an operation item to remove noise and  $\{\bullet\}$  is the tool of the averaging process. The first mode can then be computed as  $IM_1 = \tilde{\kappa}(t) - R_1(t)$ .

The second residue  $R_2$  can be computed as  $R_1(t) + \chi_1 \overline{\overline{D}}_2(\overline{\overline{\omega}}^{(i)}(t))$ , and the second mode  $IM_2$  is obtained:

$$IM_2 = R_1(t) - R_2(t) = R_1(t) - \left\{ \overline{\overline{L}}(\chi_1 \overline{\overline{D}}_2(\overline{\overline{\omega}}^{(i)}(t)) + R_1(t)) \right\} \quad (1)$$

For  $j = 3, 4, \dots, n$ , the  $j$ -th residue is calculated as:

$$R_j(t) = \left\{ \overline{\overline{L}}(\chi_{j-1} \overline{\overline{D}}_j(\overline{\overline{\omega}}^{(i)}(t)) + R_{j-1}(t)) \right\} \quad (2)$$

$IM_j = R_{j-1}(t) - R_j(t)$  can also be obtained. After obtaining all the modes, the original sequenc  $\tilde{\kappa}$  can be reconstructed as  $\kappa' = \sum R_j(t) + \overline{\overline{R}}(t)$ , where  $\overline{\overline{R}}$  is the residual sequence.

### 2.2 Neural network models

LSTM (long short-term memory) is a special type of RNNs. The key components of LSTM are memory cells and gates. The forget gate determines the number of the

unit state  $C(t-1)$  remaining at current moment  $C(t)$  and is calculated as  $\bar{F}_{\sigma, \bar{b}, \bar{\omega}}(t) = \sigma(\bar{b}_f + \{x_t, h_{t-1}\} * \bar{\omega}_f)$ . The number of inputs  $x(t)$  stored in the cell state  $C(t)$  is determined in the calculation process of the input gate  $\bar{I}_{\sigma, \bar{b}, \bar{\omega}}(t) = \sigma(\bar{b}_i + \{x_t, h_{t-1}\} * \bar{\omega}_i)$ . Finally, the output gate controls the number of unit states  $C(t)$  to be output to the present output value  $h(t)$  and is given by  $\bar{O}_{\sigma, \bar{b}, \bar{\omega}}(t) = \sigma(\bar{\omega}_o * \{h_{t-1}, x_t\} + \bar{b}_o)$  where  $\bar{b}$  and  $\bar{\omega}$  are bias and weight, respectively. The calculation principle of GRU (gated recurrent unit) is very similar to LSTM. The difference is that GRU combines the forgetting gate and input gate in LSTM algorithm into update gate, so GRU consists of two gates, the update gate and the reset gate.

The hidden layer of CNN (convolutional neural network) consists of convolution  $C_L$ , pooling  $P_L$  and full connection  $F_L$ . The convolution process is represented as  $C_{x,y} = \sum_i^{p*q} \bar{\omega}_i v_i$ , which is the sum of the product of the kernel weight and the brightness of the corresponding element in the input image. The main goal of pooling is to reduce the feature space of the maps. The fully connected layer is greatly important in combining the extracted features to obtain the output.

TCN (temporal convolutional networks) is suitable for sequence model construction under causal constraints, that is, the output  $\{\hat{y}_0, \hat{y}_1, \dots, \hat{y}_t\}$  can only be predicted based on the past observation  $\{x_0, x_1, \dots, x_t\}$ . Therefore, TCN can be designed as a nonlinear function with the mapping  $f : X^T \rightarrow Y^T$ . In addition, TCN also adds the dilated convolution and residual block to better extract historical information.

QRNN (quasi-recurrent neural networks) is the LSTM acceleration algorithm, including two components of convolution and pooling. In the convolution operation, the output of the input, forget and output gates can be expressed as  $Z = \tanh(W_z * X)$ ,  $F = \sigma(W_f * X)$  and  $O = \sigma(W_o * X)$ , where  $X$  is the input,  $W_z$ ,  $W_f$  and  $W_o$  are the convolution filters. There are three ways the pooling process can reduce the number of features, named f-pooling, fo-pooling and ifo-pooling based on the number of gates used.

ANFIS (adaptive neuro-fuzzy inference system) is a neural network based on fuzzy reasoning. The first layer is a fuzzy layer.  $\bar{O}_{i=1,2}^1 = \mu_{A_i}(x)$  and  $\bar{O}_{j=1,2}^1 = \mu_{B_j}(y)$  are output functions where  $x$  and  $y$  are the inputs with the respective membership functions  $\mu_{A_i}$  and  $\mu_{B_j}$ . The second layer calculates the weights of each membership function according to the previous outputs. The third layer normalizes the weights as  $\bar{O}_i^3 = \bar{w}_i = \bar{w}_i / (\bar{w}_1 + \bar{w}_2)$ . The fourth layer provides the output of the rule inference  $\bar{O}_i^4 = \bar{w}_i \bar{F}_i$ . The last layer generates the sum of each output  $\bar{O}_i^5 = \sum \bar{w}_i \bar{F}_i = (\sum \bar{w}_i \bar{F}_i) / \sum \bar{w}_i$ .

ELM (extreme learning machine) is a kind of feedforward neural network that includes input, hidden and output layers. The thresholds  $b$  and input weights  $\omega$  are randomly generated. The input and output are  $\bar{X} = (x_i^1, x_i^2, \dots, x_i^n) \in \mathbb{S}^n$  and  $\bar{T} = (t_i^1, t_i^2, \dots, t_i^m) \in \mathbb{S}^m$ . The hidden layer output is  $\bar{H}_{i=1, \dots, n}^{\omega, b}(x) = \bar{F}(x^T \bar{\omega}_i + b_i)$ , where  $\bar{F}(\bullet)$  is the activation function. The final output is  $\bar{O}_n^{\omega, b, \theta}(x) = \sum_{i=1}^n \bar{H}_i(x) \bar{\theta}(i)$ , where the output weights are  $\bar{\theta} = (\bar{\theta}_1, \dots, \bar{\theta}_n)$ .

BPNN (back propagation neural network) consists of input, hidden and output layers, and the calculation is:  $y_i = f_i \left( \mu_j + \sum_{m=t-n}^{t-1} \mu_{jm} y_m \right) (0 \leq \mu_j, \mu_{jm} \leq 1)$ ,  $y_t = f_0 \left( \lambda_0 + \sum_{j=1}^I \lambda_{0j} y_j \right) (0 \leq \lambda_0, \lambda_{0j} \leq 1)$ , where  $y_m$  and  $y_j$  are the inputs of the input and hidden layers,  $y_t$  is the predicted value at time  $t$ .  $N$  and  $I$  are the number of nodes in the input and the hidden layers. In the hidden and output layers,  $\mu_j$  and  $\lambda_0$  are the threshold values,  $\mu_{jm}$  and  $\lambda_{0j}$  are weights,  $f_i$  and  $f_0$  are activation functions.

On the basis of BPNN structure, ENN (elman neural network) adds a continuation layer to the hidden layer as a delay operator to achieve the purpose of memory. The learning process is:  $x(k) = f(w_1 x_c(k) + w_2(u(k-1)))$ ,  $y(k) = g(w_3 x(k))$ , where  $y$  is the  $m$ -dimensional output vector,  $x$  is the unit vector of  $n$ -dimensional middle layer,  $u$  is the  $r$ -dimensional input vector,  $w_i (i=1,2,3)$  is the connection weight of each layer,  $g(\cdot)$  and  $f(\cdot)$  are activation functions of output and middle layer neurons respectively.

GRNN (general regression neural network) is a kind of radial basis neural network, which is composed of input, pattern, summation and output layers.  $p_i = \exp[-(X - X_i)^T (X - X_i) / 2\sigma^2]$   $i=1,2,\dots,n$  is the neuron transfer function of the pattern layer, where  $X$  is the input variable and  $X_i$  is the learning sample of the  $i$ -th neuron. The output of neuron  $j$  can be calculated as  $y_j = S_{Nj} / S_D$ , where  $S_{Nj}$  and  $S_D$  are the arithmetic sum and weighted sum of neurons at the pattern layer.

### 2.3 Multi objective grey wolf optimizer

Mirjalili et al. first proposed the MOGWO algorithm, who were inspired by social leadership and hunting technique of grey wolves [29, 34]. The alpha wolf  $\alpha_w$  is defined as the fittest solution, and the beta wolf  $\beta_w$  and delta wolf  $\delta_w$ , the second and third best solutions, respectively. The other candidate approaches are the omega wolves  $\omega_w$ .  $\alpha_w$ ,  $\beta_w$ , and  $\delta_w$  play a key role in capturing prey, and  $\omega_w$  follow  $\alpha_w$ ,  $\beta_w$ , and  $\delta_w$  to catch prey.

**Definition 1 Encircling process.** During the hunting of prey, the grey wolf location is updated as  $\overline{L}_{wolf}^{t=\alpha,\beta,\delta}(t+1) = \overline{L}_{prey}^t - H \otimes \Delta \overline{D}^t$ , where  $\overline{L}_{prey}^t$  and  $\overline{L}_{wolf}^{t=\alpha,\beta,\delta}$  represent the location of prey and grey wolf, respectively, and  $\Delta \overline{D}^{t=\alpha,\beta,\delta} = \left| C \otimes \overline{L}_{prey}^t - \overline{L}_{wolf}^t \right|$  is the distance between the grey wolf and its prey.  $C$  and  $H$  are coefficient vectors that are calculated as  $C = 2 \otimes \gamma_2$  and  $H = 2\zeta \otimes \gamma_1 - \zeta$ , respectively, where  $\zeta$  is the convergence factor, which decreases linearly from 2 to 0 with the number of iterations, and  $\Upsilon$  is a random vector  $\Upsilon = [\gamma_1, \gamma_2] \in [0, 1]$ .

**Definition 2 Hunting behavior.** Suppose that  $\alpha_w$ ,  $\beta_w$  and  $\delta_w$  have a better command of the potential location of the prey and their distance from the prey is:

$\Delta \overline{D}^{t=\alpha,\beta,\delta} = \left| C^t \otimes \overline{L}_{prey}^t - \overline{L}_{wolf}^t \right|$ . The current location of the wolves is then obtained as

$\overline{L}_{wolf}^{t=\alpha,\beta,\delta} = \overline{L}_{prey}^t - H^t \otimes \Delta \overline{D}^t$ , and the location of  $\omega_w$  can be calculated as

$$\overline{L}_{wolf}^{\omega} = \sum_{t=\alpha,\beta,\delta} \overline{L}_{wolf}^t / 3.$$

**Definition 3 Exploitation.** When  $H \in [-1,1]$  is random vector, the wolves can move at will between themselves and the prey. This narrows down the estimated location of the prey provided by  $\alpha_w$ ,  $\beta_w$  and  $\delta_w$ .

**Definition 4 Searching prey.** When  $|H| > 1$ , the wolf is forced to separate from its prey while  $|H| < 1$  helps to converge towards the prey. Moreover, the random vector  $C \in [0, 2]$  facilitates the discovery of new solutions.  $C > 1$  indicates that the location of the wolf has a great influence on the prey and  $C < 1$  indicates that the location of the wolf has little effect on the prey.

**Definition 5 Archive.** The archive is a store tool that saves or retrieves non-dominated Pareto optimal solutions.

**Definition 6 Leader selection mechanism.** This selection mechanism adopts the roulette wheel approach of  $P_i = c / N_i$  to choose the non-dominated Pareto optimal solution where  $c$  is a fixed value and  $c > 1$ .  $N$  denotes the sum of Pareto optimal solutions obtained.

## 2.4 Multi objective problems (Mop)

In multi-objective problems, it is critical to find vector solutions. The concept of Pareto dominance is designed to facilitate the choice of the vector solutions. The Pareto optimal solution is defined as follows:

(1)  $\bar{\omega}^1$  is considered to dominate  $\bar{\omega}^2$ , i.e.,  $\bar{\omega}^1 \succ \bar{\omega}^2$ , if and only if  $\bar{\omega}^1$  and  $\bar{\omega}^2$  meet:  $[\forall p \in \{1, 2, \dots, t\}, \bar{F}_p(\bar{\omega}^1) \leq \bar{F}_p(\bar{\omega}^2)] \wedge [\exists q \in \{1, 2, \dots, t\}, \bar{F}_q(\bar{\omega}^1) < \bar{F}_q(\bar{\omega}^2)]$ , where  $\bar{F}$  is a function and  $t$  denotes a vector of numbers.

(2) The solution  $\bar{\omega}^1$  is called the Pareto optimal solution if the conditional equality  $\neg \exists \bar{\omega}^i \in \mathbb{S}, \bar{\omega}^i \prec \bar{\omega}^1$  is satisfied, where  $\mathbb{S}$  denotes solution space.

(3) The Pareto optimal solution set  $\bar{P}^s$  includes all the Pareto optimal solutions and can be expressed as  $\bar{P}^s = \{ \bar{\omega} \mid \neg \exists \bar{\omega}^i \in \mathbb{S}, \bar{\omega} \succ \bar{\omega}^i \}$ .

To improve the precision and stability of the combined system, the MOGWO objective function is defined as:

$$\min \begin{cases} \bar{F}^1 = (1/Q) \sum_i^Q |(P^i - A^i) / A^i| \times 100\% \\ \bar{F}^2 = std(P^i - A^i) \quad i = 1, \dots, Q \end{cases} \quad (3)$$

where  $\bar{F}$  is the objective function,  $P$  and  $A$  represent the forecasted and true values.

## 2.5 The Pareto solution proof

The objectives in MOPs may often conflict with one another. The solutions in such problems can usually be expressed as the Pareto solution ( $\hat{\lambda}^*$ ). For MOPs, the Pareto solution ( $\hat{\lambda}^*$ ) that satisfies  $\neg \exists \mathcal{G} \in \Omega_{s,t}, FIT(\hat{\lambda}^*) < FIT(\mathcal{G}^*)$  is adopted rather than the accurate solution. *Arc* is a tool for storing the non-dominated solutions ( $\hat{\lambda}'$ ); however, the storage capacity of *Arc* is limited and has the upper bound of  $\bar{Y}$ , that is,  $Y \prec \bar{Y}$ . Hence, in the process of updating *Arc*, it is necessary to compare the new solution  $\hat{\lambda}'$

and the present non-dominated solutions  $\{\hat{\lambda}_1^p, \hat{\lambda}_2^p, \dots, \hat{\lambda}_Y^p\}$  in  $Arc$ . When  $\hat{\lambda}' \succ \hat{\lambda}_i^p$  or  $\hat{\lambda}' \sim \hat{\lambda}_i^p$ ,  $i \in [1, Y]$ ,  $\hat{\lambda}'$  is added into  $Arc$  and  $\hat{\lambda}_i^p$  is removed or ranked behind  $\hat{\lambda}'$ . Once the  $Arc$  capacity has reached the upper bound  $Y = \bar{Y}$ , the most crowded segments will be removed with the deletion probability  $Pd_i = Y_i / c$  ( $c > 1$ ). Then, the roulette-wheel technique is employed to compare the present solution with  $\hat{\lambda}'$  with the probability  $Pd_i = Y_i / c$  ( $c > 1$ ) to determine the Pareto optimal solution  $\hat{\lambda}'$ . The pseudocode is listed as **Table 2**.

## 2.6 Uncertainty prediction

Interval prediction is proposed to quantify the uncertainty. According to maximum likelihood estimation (MLE), Weibull, Gamma, Rayleigh and Lognormal distribution are adopted to fit the data. Interval prediction results of CFM is testified and compared with basic models, the upper and lower bound is expressed as:

$Up^{i-th} = Fr^{i-th} + Dis_{1-\alpha/2} \cdot \sigma_{Dis}^* / \sqrt{n}$ ,  $Lo^{i-th} = Fr^{i-th} - Dis_{\alpha/2} \cdot \sigma_{Dis}^* / \sqrt{n}$ , where  $Dis_{1-\alpha/2}$  and  $Dis_{\alpha/2}$  are the critical values of optimal distribution and  $\alpha$  is the significance level ( $\alpha=0.05, 0.1$  and  $0.2$  in this study).

## 3. Flow of the combined forecasting system

In this study, a strategy of combining interval prediction with point prediction is adopted. A smooth sequence submodel is first obtained using the ICE data preprocessing technique. Then, some single neural models are applied to forecast a stable sequence and obtain the forecasted values  $\bar{F} = (\hat{f}_1, \hat{f}_2, \hat{f}_3, \hat{f}_4)$ . In addition, the optimization operator is used to provide the most reasonable weights  $\bar{W} = (\omega_1, \omega_2, \omega_3, \omega_4)$  to combine the forecasted values in  $\bar{F}$ . Finally, confidence intervals of 80%, 90%, and 95% are set for the experiment. The main framework is illustrated in Fig.1.

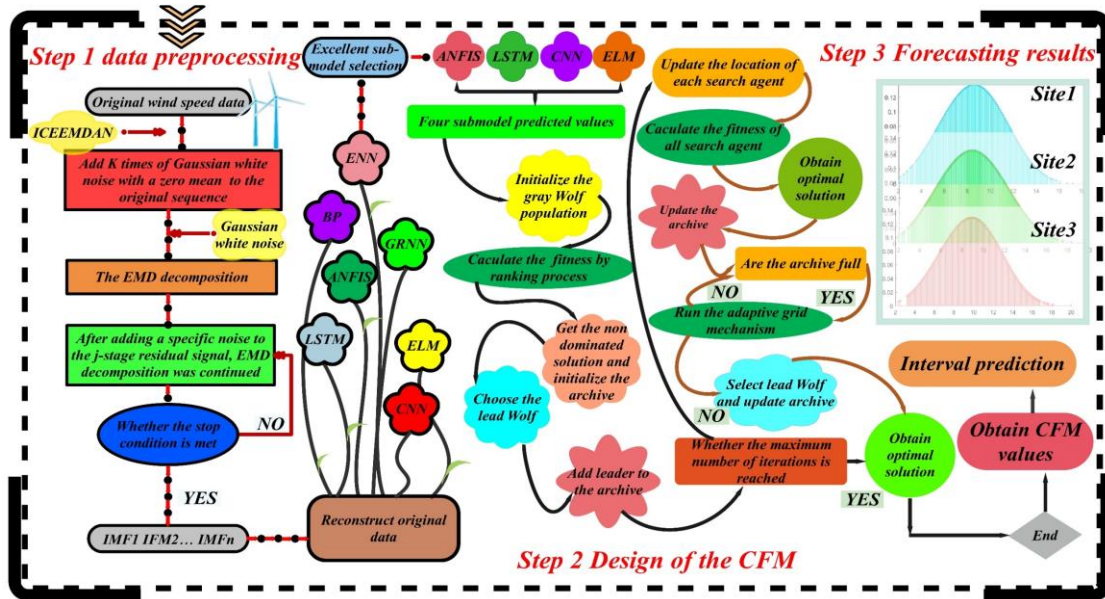

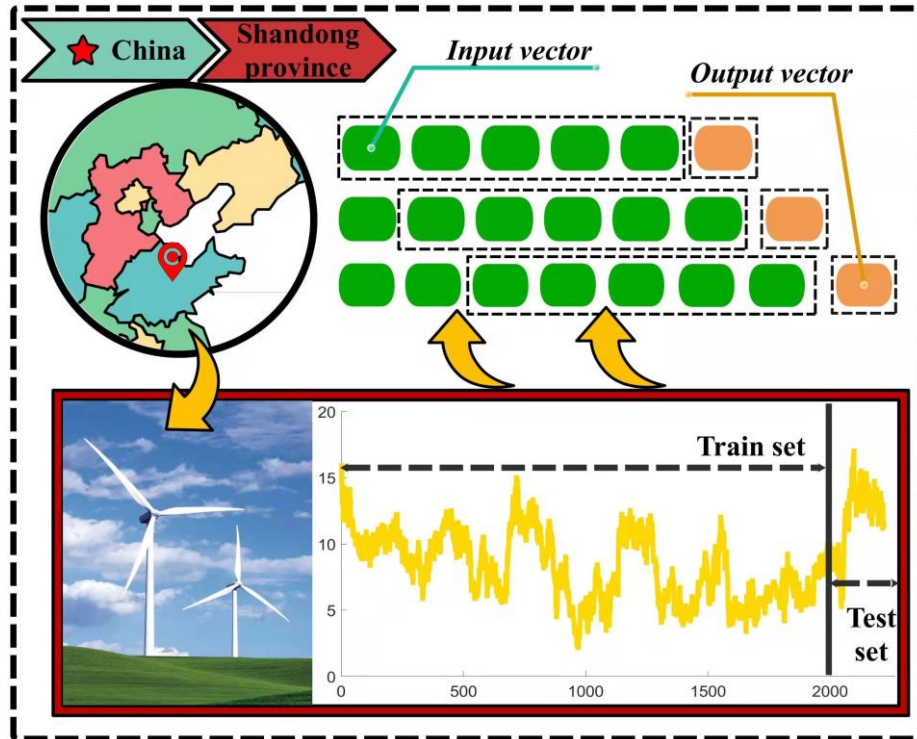

Fig.1 The main structure of this paper

## 3.1 Information of datasets

A wind power plant in Penglai ( $37^{\circ}48'N$   $120^{\circ}45'E$ ), Shandong Province, China, is used as the example. Seven sites are chosen to verify the performance of the proposed system, which include 10-min, 20-min and 30-min intervals. Besides, seven sites have the same sample size of 2220. The first 2000 samples are used for training, and the remaining 220 are used for testing. The details of the dataset are presented in **Table 3** and the features of the dataset are also visually depicted in **Fig. 2**.

**Table 3** Datasets.

SET	Sample	Size	Indicators(m/s)			
			Maximun	Minimun	Mean	Std.
Site1: 10-min	Total samples	2220	17.2000	2.0000	8.5566	2.8012

### 3.2 Metrics

In the point prediction, six commonly used indicators are applied to evaluate

model performance, namely **RMSE**, **MAE**, **MAPE**, **R<sup>2</sup>**, **IA** and **PE**, which can better reflect the prediction accuracy. The smaller the index values of **RMSE**, **MAE** and **MAPE** are, the higher the prediction accuracy of the models are, while **R<sup>2</sup>** and **IA** are opposite. Three indicators named **FINAW**, **AWD**, and **FICP** are designed for interval forecasting. **FINAW** calculates the width of the interval. **AWD** is used to estimate the degree of deviation of the interval. **FICP** measures the extent to which ranges cover true values. The detailed information of metrics is presented in **Table 4**.

**Table 4** Metrics.

Metric	Expression	Definition
<b>RMSE</b>	$RMSE = \sqrt{(1/Q) \sum_{i=1}^Q (F_i - A_i)^2}$	Root mean square error
<b>MAE</b>	$MAE = (1/Q) \sum_{i=1}^Q  F_i - A_i $	Mean absolute error
<b>MAPE</b>	$MAPE = (1/Q) \sum_{i=1}^Q  (F_i - A_i) / A_i  \times 100\%$	Absolute percentage error mean
<b>R<sup>2</sup></b>	$R^2 = 1 - \frac{\sum_{i=1}^Q (F_i - A_i)^2}{\sum_{i=1}^Q (F_i - \bar{A})^2}$	Coefficient of determination
<b>IA</b>	$IA = 1 - \frac{\sum_{i=1}^Q (A_i - F_i)^2}{\sum_{i=1}^Q ( A_i - \bar{A}  +  \bar{A} - F_i )^2}$	Consistency of the predicted results
<b>PE</b>	$PE(i) = (F_i - A_i) / A_i \times 100\%$	The percentage of the predicted value in a specified error range
<b>FICP</b>	$FICP = \left( \sum_{i=1}^Q C_i / Q \right) \times 100\%$	Coverage probability of the forecast interval
<b>FINAW</b>	$FINAW = \sum_{i=1}^Q (U_i - L_i) / FR$	Normalized averaged width of the forecast interval
<b>AWD</b>	$AWD_i = \begin{cases} (A_i - U_i) / (U_i - L_i) & A_i > U_i \\ 0 & A_i \in [L_i, U_i] \\ (L_i - A_i) / (U_i - L_i) & A_i < L_i \end{cases}$ $AWD = \left( \sum_{i=1}^Q AWD_i \right) / FR$	<b>AWD<sub>i</sub></b> denotes the cumulative deviation of the forecast interval and <b>AWD</b> is the mean of cumulative deviation

**Note:**  $F_i$ ,  $A_i$  represents the forecasting and actual value of  $i$ -th. In the point prediction evaluation index,  $\pm 5\%$ ,  $\pm 10\%$  and  $\pm 15\%$  error range are chosen to calculate the index PE; In the interval prediction evaluation index, if  $A_i$  belongs to  $[U_i, L_i]$ , then  $c_i=1$ , otherwise  $c_i=0$ ; FR means the range of predicted values.

### 3.3 Model parameter setting

The parameters for the neural network approaches are presented in **Table 5** and those for MOGWO and ICE in **Table 6**.

**Table 5** Parameters of single models.

Model	Symbol	Meaning	Value	Setting reasons
<b>BPNN</b>	$Tg$	Training goal	0.00004	Preset
	$Tf_{hid}$	Activation function of hidden	tansig	Preset
<b>ENN</b>	$E_{max}$	The maximum epochs	1000	Trial- error method
	$Tg$	Training goal	0.00004	Preset
<b>ELM</b>	$Tf$	Activation function of hidden	sig	Preset
	$C_{anf}$	The number of the cluster	10	Preset
<b>ANFIS</b>	$E_{max}$	The maximum epochs	1500	Trial- error method
	$S_{GRnn}$	Spread	1	Preset
<b>GRNN</b>	$Lr$	Training learning rate	0.005	Preset
	$E_{max}$	The maximum epochs	2000	Trial- error method

CNN	$Lr$	Training learning rate	0.005	Preset
	$B_{min}$	MiniBatchsize	16	Trial- error method
GRU	$H_L$	Numbers of hidden layers	40	Trial- error method
	$E_{max}$	The maximum epochs	2000	Preset
TCN	$H_L$	Numbers of hidden layers	50	Trial- error method
	$E_{max}$	The maximum epochs	500	Preset

**Table 6** Parameters of ICE and MOGWO.

Model	Symbol	Meaning	Value	Setting reasons
ICE	$Iter_{max}$	The maximum number of iterations	1000	Trial- error method
	$NR$	Realization Number	100	Trial- error method
	$Iter_{max}$	The maximum number of iterations	100	Trial- error method
	$As$	Archive size	100	Trial- error method
MOGWO	$P_s$	Population size	200	Trial- error method
	$\alpha$	Grid inflation	0.1	Preset
	$g$	Sum of grids per dimension	10	Preset
	$\beta$	Leader selection pressure	3	Preset

## 4. Experiment results

In this section, the results of the four comparative experiments and two validation tests to evaluate CFM are shown.

### 4.1 Selection of excellent sub models

Seven single predictive models named ANFIS [35, 36], LSTM [37, 38], CNN [39, 40], ELM [41-43], BPNN [44], GRNN [45, 46], and ENN [47] were chosen to forecast the original sequence in this study. To choose the most suitable models for improving the accuracy of CFM, the SEM strategy was developed [48]. The strategy is introduced below:

(1) The MAPE, MAE, and RMSE of every sub-model are calculated for one hundred iterations.

(2) Each index value is normalized as, for example,

$$\overline{MAE}_i = ((MAE_i - \min_{1 \leq i \leq Q}(MAE)) / (\max_{1 \leq i \leq Q}(MAE) - \min_{1 \leq i \leq Q}(MAE))) \quad (4)$$

(3) Weights are assigned to each index value and the SEM value is calculated as

$$SEM_i = (1/3) * \overline{MAE}_i + (1/3) * \overline{MAPE}_i + (1/3) * \overline{RMSE}_i .$$

The SEM values are listed in **Table 7**. A smaller SEM value indicates a higher model precision. Based on the results, ANFIS, LSTM, CNN, and ELM were chosen as the sub-models.

**Table 7** Results of SEM.

SEM	Model						
	GRNN	LSTM	ELM	BPNN	ANFIS	CNN	ENN
Site1_SEM	0.3300	0.3021	0.3797	0.2458	0.2871	0.2590	0.2589
Site2_SEM	0.2814	0.1587	0.2240	0.3657	0.3125	0.2200	0.4129
Site3_SEM	0.3251	0.4011	0.2134	0.2948	0.2250	0.3100	0.3201
SEM*	0.3122	<b>0.2873</b>	<b>0.2724</b>	0.3021	<b>0.2749</b>	<b>0.2630</b>	0.3306

**Note:** \* mean the average of SEM values of all sites.

### 4.2 Experiment I: Comparison between CFM and basic models

To demonstrate the performance of CFM, seven individual models were used for comparison in Experiment I. The results are as shown in **Table 8** and **Fig. 3**.

In **Table 8**, CFM exhibited the smallest error with MAPE, MAE and RMSE values of 2.8645%, 0.3217 and 0.4114 at site1. At site2, CFM exhibited the best performance

with the MAPE value of 2.1843% compared to the other models, which had an average MAPE value of 4.8747%. The superior precision of CFM was thus verified. The IA and  $R^2$  can better reflect the agreement between the actual and the forecast data. At site1, CFM showed a better performance with the values of  $R^2$  and IA exceeding 97%, which was a 10% improvement in IA and  $R^2$  over the best model, GRNN.

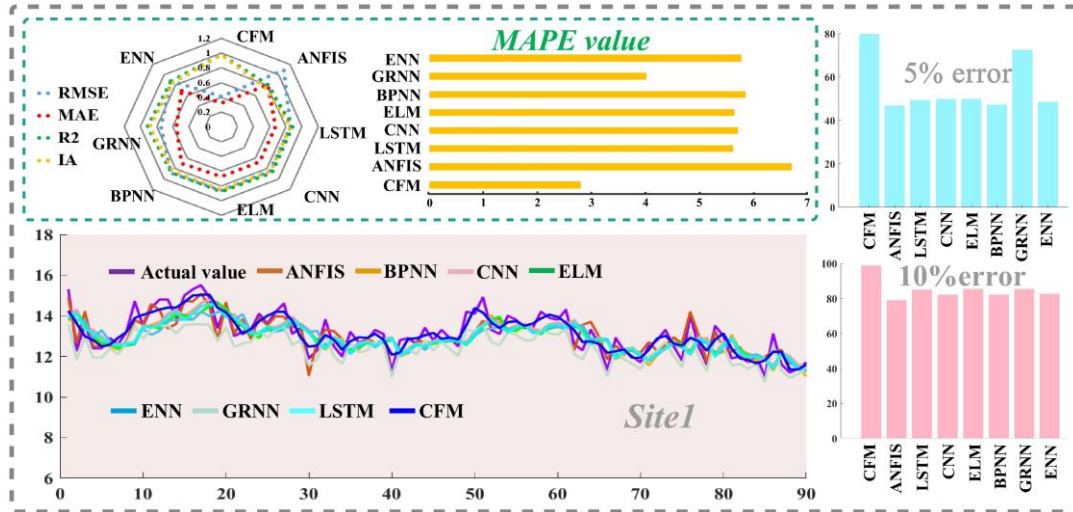

Fig.3 Results of CFM and basic models

#### 4.3 Experiment II: Comparison between CFM and single model based on ICE

Experiment II was designed to contrast the accuracy of CFM and other models based on ICE. The results are presented in **Table 9** and **Fig.4**. The following conclusions can be drawn from the results:

It is obvious that CFM achieved the best prediction results at site1, with MAPE, MAE and RMSE values of 2.8645%, 0.3217, and 0.4114. For site2, the worst-performing model was ICE-ENN with MAPE exceeding 3.1044%. By contrast, the corresponding index value for CFM was 1% lower than that of ICE-ENN. For site3, CFM still exhibited the excellent performance with  $R^2$  exceeding 97%. The prediction error PE of CFM in the range of 5%, 10%, and 15% was greater than 80%, 90% and 95%, respectively. Obviously, CFM had more excellent prediction accuracy.

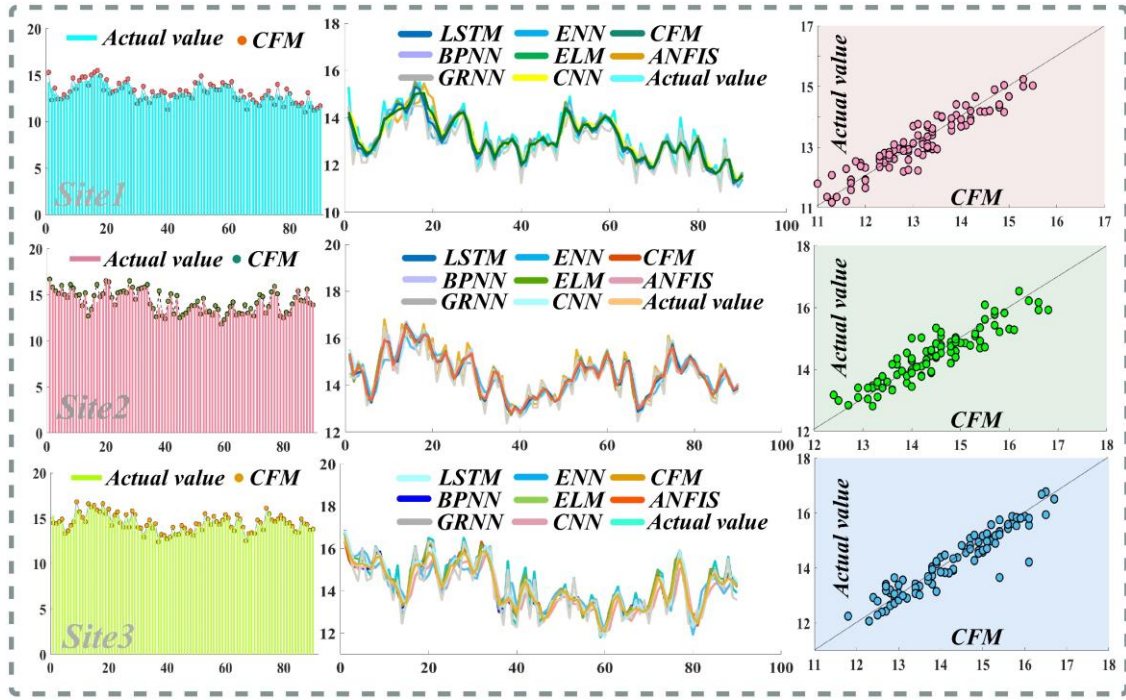

Fig.4 Results of CFM and denoising models

#### 4.4 Experiment III: Comparison between CFM and models with other denoising strategy

In this section, three denoising strategies, namely, CEE, EMD, and EEMD, were chosen to verify the predictive abilities of CFM, and the detailed results are presented in **Table 10**. The following conclusions can be drawn:

For site1, for the worst-performing EEMD-based model, the values of MAPE, MAE and RMSE were 4.6335%, 0.6592 and 0.6368, which far exceeded the corresponding values for CFM. For site2,  $MAPE_{EMD}=3.3387\%$  was obtained for the best classical model, which was based on EMD. In comparison, the smaller value of  $MAPE_{CFM}=2.1843\%$  was obtained for CFM. Finally, for site3, the prediction errors of the comparison models in the range of 5% were almost less than 80%. It is not difficult to find that CFM performed better with  $PE_{CFM}^{5\%}$  exceeding 80%.

#### 4.5 Experiment IV: Comparison between CFM and other optimization strategies

In this part, three optimization strategies called MOGOA, MOALO and MODA were designed to evaluate the predictive precision of CFM. The calculation results are listed in **Table 11**. It can be easily seen that the CFM had excellent performance. For example, for site1, the  $MAPE_{CFM}=2.8645\%$  of CFM was 0.2%, 0.02% and 0.05% lower than those of MOGOA, MOALO, and MODA, respectively. In addition, only the  $R^2$  of CFM exceeded 95%, while its IA exceeded 97%. It can be found from the above evaluation index values that CFM has better performance in forecasting.

**Table 8** The performances of CFM and basic models.

**Note:** The table lists the predicted results of CFM and basic models. The blacked part represents the evaluation index value of CFM. The equation of metrics are defined as:  $PE(i) = (F_i - A_i) / A_i \times 100\%$  ,  $MAE = (1/Q) \sum_{i=1}^Q |A_i - F_i|$  ,  $MAPE = (1/Q) \sum_{i=1}^Q |(A_i - F_i) / A_i| \times 100\%$  ,  $R^2 = -\sum_{i=1}^Q (A_i - F_i)^2 / \sum_{i=1}^Q (F_i - \bar{A})^2 + 1$  ,  $RMSE = ((1/Q) \sum_{i=1}^Q (A_i - F_i)^2)^{(1/2)}$  ,  $IA = -\sum_{i=1}^Q (A_i - F_i)^2 / \sum_{i=1}^Q (|A_i + \bar{A}| + |F_i - \bar{A}|)^2 + 1$  . In addition, GRU, TCN and QRNN are introduced in experiments I and II to make a more complete comparison.

## 4.6 Uncertainty forecasting

An interval estimate is based on a point estimate and can increase the prediction reliability and certainty [31]. In this subsection, four distributions were chosen to fit the sequence based on maximum likelihood estimation (MLE). They are Weibull, Gamma, Rayleigh and Lognormal distribution, which are shown in **Table 12**. After analysis, the Weibull distribution was adopted for the three sites, and the detailed parameter settings are presented in **Table 13**. Then, three indicators named FINAW, AWD, and FICP were designed for interval forecasting. The detailed results are depicted in **Fig.5** and **Table 14**.

The indicators were evaluated for the probabilities  $P_1=95\%$ ,  $P_2=90\%$ , and  $P_3=80\%$ . These probabilities can be expressed as  $(1-\alpha)\times 100\%$ . It is clear that the prediction accuracy at the significance level of  $\alpha=0.05$  was superior to the accuracies at  $\alpha=0.1$  and  $\alpha=0.2$ . At the significance level of  $\alpha=0.05$ , the FICP for CFM at every site exceeded 85%. In addition, at  $\alpha=0.1$ , the FICP for CFM was between 80% to 85%. The similar values of AWD and FINAW at different significance levels implies that most of the actual values fell within the predicted ranges and that CFM achieved excellent performance.

**Fig.5** The interval forecasting results

## 5. Discussion

In this section, the results of improvement ratio, hyperparametric analysis, and the exploration of input and multi-step forecasting, operation time, comparative analysis and practical applicability are discussed to further analyze the above experimental results.

### 5.1 Improvement ratio

The aim of the improvement indicator is to quantify the improvement in the predictive precision of CFM.  $IR_{MAPE}$ ,  $IR_{MAE}$  and  $IR_{RMSE}$  are designed to represent the improvement ratio. The details are shown in **Table 15**. For example, the models based on ICE for site1 had the values of  $IR_{MAPE}^{\text{ANFIS}}=9.2670\%$ ,  $IR_{MAPE}^{\text{LSTM}}=4.1438\%$ ,  $IR_{MAPE}^{\text{CNN}}=19.0262\%$ ,  $IR_{MAPE}^{\text{ELM}}=4.5895\%$ , which shows that the advantages of each model were

combined in CFM. For the different denoising methods, it is clear from the average value of 34% for  $\overline{\mathbf{IR}}_{MAPE}^{ave}$  in these models that ICE played a key role in improving the forecasting accuracy. The various optimization strategies achieved an average value of 7.3309% for  $\overline{\mathbf{IR}}_{MAPE}^{ave}$ . This implies that MOGWO could improve forecasting ability. There is no doubt that CFM was superior to the single models and the combined strategy achieved excellent prediction results.

## 5.2 Hyperparametric analysis

To investigate the influence of key parameter changes on the proposed model, only one key parameter was changed each time while the other parameters remained the same in this section. We changed the values of five parameters in the ICE and MOGWO algorithms. For ICE, the maximum iteration parameters values were [500, 3000] and the number realizations were [50, 100, 300]. For MOGWO, the archive size parameters values were [200,300,500], the maximum iteration parameter values were [50,150, 200], and the population sizes were [50,70,120]. The calculation results are shown in **Table 16**. With the change of parameter values, the precision of the model also changed. For example, at site1, the number realizations were set to 50,100 and 300. When 100 was selected, the proposed model achieved good MAPE values with 2.8645%, 2.1843% and 2.8727% in three sets. In general, it is not difficult to find that the parameter values selected in this paper perform better.

## 5.3 Influence of input step and multi-step prediction

This section adds sites 4-7 to better discuss the performance of the proposed model. Specifically, sites 4-5 use wind speed data at 20-minute intervals and sites 6-7 apply wind speed data at 30-minute intervals. The sample size and experimental mechanism are consistent with the above. Considering the neatness and symmetry of the table content, in sections 5.3.1 and 5.3.2, site1 (10-min), site2 (10-min), site4 (20-min), site5 (20-min), site6 (30-min) and site7 (30-min) are used to test the performance of the proposed model.

### 5.3.1 Influence of input step

To analyze the influence of different input steps on prediction more accurately, the input steps  $\lambda$  were adjusted to 3, 4 and 6, and a comparative test was performed to further explore the performance of the proposed forecasting system. From **Table 17**, it is easy to see that for the 10-min sites, when the input step  $\lambda$  was 3, the prediction errors of  $\mathbf{MAPE}_{\lambda=3}^{site1} = 3.0833\%$  and  $\mathbf{MAPE}_{\lambda=3}^{site2} = 2.4134\%$  were larger at those of other steps. For the 20-min sites,  $\mathbf{PE}_{\lambda=3}^{5\%}$  and  $\mathbf{PE}_{\lambda=4}^{5\%}$  are less than 70%, which implies that better forecasting results were obtained by CFM compared to  $\mathbf{PE}_{\lambda=5}^{5\%} = 69.33\%$  at site4 and  $\mathbf{PE}_{\lambda=5}^{5\%} = 72.22\%$  at site5. The prediction accuracy for the 30-min sites was obviously inferior to those of the previously mentioned sites; however, the input step 5 still performed well. From the above analysis, it can be concluded that as the time interval increased, the prediction accuracy decreased continuously, but the best performance was still obtained when the input step was 5.

### 5.3.2 Influence of multi-step prediction

The multistep forecasting ability of the proposed system is explored in the subsection. The details of the two-and three-step predictions are presented in **Table 18**.

For site1, which had 10-min intervals, the smallest errors of  $\text{MAPE}_{CFM}^{step2} = 4.4556\%$ ,  $\text{MAE}_{CFM}^{step2} = 0.5848$  were achieved by CFM compared to the other models, which had the average errors with MAPE and MAE values of 5.0829% and 0.7960 for two-step predictions. In addition, the accuracy of the three-step prediction was obviously lower than that of the two-step prediction, but the CFM still achieved the good result with  $R_{CFM}^2$  greater than 90%.

The accuracy decreased with longer interval times. For example, for the 20-min predictions by CFM, the MAPE values in two-step was 6.5225% at site4, which exceeded the values for the 10-min sites. For the 30-min predictions, the prediction error  $\text{MAPE}_{CFM}^{step2}$  increased to 9% at site6. These results indicate that the prediction system may be more suitable for short-term wind speed prediction.

#### 5.4 Operation time

Table 19 shows the mean operation time of all models used in this paper. It is clear that the proposed system had the longest calculation time, at 264.8361s. For basic models, the running time of BPNN was 0.4111, which was the least time in all models. The computation time of models based on ICE denoising algorithm was also short, which was 57.9170s, 19.2999s, 65.4855s, 36.4029s, 20.4532s, 18.9124s and 22.8657s. In addition, when applying other noise reduction algorithms or optimization algorithms, the time spent on combined models increased significantly, which was in the 100s to 200s range. Although the time consumed of the proposed model was longer than other models, it had superior predictive power. Its time was within the acceptable range and did not affect its practical application greatly.

**Table 19** Computing time.

Model	Computation time(s)	Model	Computation time(s)

#### 5.5 Comparative analysis

Through the experiments above, the validity of the proposed model is proved. However, the results based only on the experimental mechanism in this paper may not be convincing. Therefore, in order to be fair, this section compares the proposed model with other similar studies. Specifically, Niu's model [32], Shao's model [29] and Liu's model [23] are used for comparative study. Niu et al. designed the combined model based on data preprocessing and optimization algorithm for wind speed forecasting, which obtained high accuracy with the smallest MAPE value of 2.89%. However, Niu et al. ignored the importance of uncertain predictions and the influence of parameters on model performance was not considered. Shao et al. used the same MOGWO algorithm and proposed a combined model based on decomposition-integration, but also lacked the exploration of uncertainty prediction and the influence of model

1 parameters. Liu et al. not only applied the improved optimization algorithm to point  
2 prediction and interval prediction of wind speed, but also considered the influence of  
3 different seasons on wind speed prediction. However, Liu's model lacked comparison  
4 with other literatures, and the results of parameter adjustment were not fully  
5 demonstrated. **Table 20** presents the comparison results of this study with other studies.

6 There is no unified comparison standard for model accuracy among different  
7 studies [49]. Therefore, to verify the accuracy of the proposed model, the evaluation  
8 index and datasets in this paper are applied in the models of Niu, Shao and Liu.  
9 Meanwhile, parameter settings are basically consistent with those in the original  
10 literature. Although the error between these models was not large, it was enough to  
11 show that the proposed model is superior to the models from comparative studies. For  
12 example, the MAPE value of the proposed model was 2.8645%, while Niu, Shao and  
13 Liu had values of 3.4181%, 4.0200% and 3.1835% respectively. The proposed model  
14 also had outstanding advantages in other indicators. Therefore, it can be reasonably  
15 concluded that the proposed model has excellent predictive ability.  
16  
17  
18  
19

## 20 **5.6 Practical applicability**

21 Efficient and timely wind speed prediction plays an important role in wind power  
22 generation system, which can not only meet people's demand for electricity, but also  
23 maximize economic benefits. Meanwhile, the proposed model in this paper can also be  
24 applied to other fields:

25  
26 **(a) Air quality forecasting.** Deep learning technology has been widely used in air  
27 monitoring, this proposed prediction system based on deep learning methods can be  
28 applied to the monitoring of air quality, for example, to timely predict air pollutant  
29 concentrations and to provide reasonable suggestions for travelling and improving the  
30 environment.  
31

32 **(b) Traffic forecasting.** In recent years, the prediction of traffic flow has become the  
33 focus of attention. This proposed system can sensitively capture the change of traffic  
34 flow, so as to reduce traffic congestion, relieve people's travel pressure and provide  
35 support for the development of intelligent transportation.  
36

37 **(c) Financial market forecasting.** This system can also be used in the prediction of  
38 future trends in stocks, funds, etc, timely providing technical support for discovery of  
39 potential financial risks.  
40  
41

## 42 **6. Conclusion and future work**

43 Wind energy has received increasing attention as a renewable energy source to  
44 address the shortages in the energy market. Nevertheless, the fluctuation and instability  
45 of wind speed still present difficulties for wind speed forecasting. An advanced wind  
46 speed prediction system was developed in this study. The ICE denoising strategy was  
47 first used to eliminate noise to obtain stationary sequences based on the de-composition  
48 and ensemble theory. Several single models were then adopted to predict the processed  
49 data. The optimal weights and final forecasting results were obtained using the  
50 MOGWO operator. The Pareto optimality of the MOGWO solutions was theoretically  
51 proven to ensure that the optimal weight vector can be obtained in the combined system.  
52 The point prediction results show that the MAPE values of the proposed model were  
53 2.8645%, 2.1843% and 2.8727% respectively. Besides, for uncertainty forecasting, the  
54 FICP values of the proposed model were 85.1697, 89.5410 and 88.0111 respectively at  
55 the significant level  $\alpha = 0.05$ . The AWD values were 0.0559, 0.0400 and 0.0361 and  
56 the FINAW values were 0.0478, 0.0404 and 0.0390. It is clear that the proposed system  
57  
58  
59  
60  
61  
62  
63  
64  
65

exhibits remarkable accuracy and stability performance. This system can hence provide accurate and real-time wind power information and contribute to wind power generation.

There are still some areas that need to be improved in future studies, for example: (1) In order to further improve the prediction accuracy, the influence of temperature, wind direction and other variables on wind speed prediction needs to be further discussed. (2) More advanced deep learning algorithms can be applied to future research to improve the accuracy of developed system. (3) Using more efficient preprocessing methods deals with unstable, random wind speed data. In addition, the effects of different preprocessing methods need to be further explored.

Site3: 10-min	Weibull	10.0906	3.1837

**Note:**  $\lambda$  and  $k$  are scale and shape parameter.

**Table 14** Interval forecasting results.

Model	Expectation probability	Site1: 10-min			Site2: 10-min			Site3: 10-min		
		FICP	AWD	FINAW	FICP	AWD	FINAW	FICP	AWD	FINAW
CFM	95%	85.1697	0.0559	0.0478	89.5410	0.0400	0.0404	88.0111	0.0361	0.0390
	90%	83.8456	0.0646	0.0364	84.6134	0.0519	0.0339	81.1961	0.0641	0.0327
	80%	80.3296	0.0796	0.0305	81.0431	0.0659	0.0264	78.2684	0.0965	0.0255

**Note:** This table lists the interval forecasting results of CFM, which can further show the accuracy of CFM. The formula of **FICP**, **FINAW** and **AWD** are:  $\text{FICP} = \left( \sum_{i=1}^o C_i / M \right) \times 100\%$ ,  $\text{FINAW} = \sum_{i=1}^o (U_i - L_i) / FR$ , if  $A_i > U_i$ , then  $\text{AWD}_i = (A_i - U_i) / (U_i - L_i)$ , if  $A_i \in [L_i, U_i]$ , then  $\text{AWD}_i = 0$ , if  $A_i < L_i$ , then  $\text{AWD}_i = (L_i - A_i) / (U_i - L_i)$ . Thus,  $\text{AWD} = \left( \sum_{i=1}^o \text{AWD}_i \right) / FR$ ,  $FR$  represents the range of predicted values.

**Table 20** Comparison results.

Authors	Published year	Algorithm	Results	Similarity	Difference					
Niu et al. [32]	2019	1. CEEMDAN 2. BPNN+GRNN+ENN+ELM +ARIMA 3. MOGOA	The combined model obtained high accuracy, the MAPE values of five data sets are 3.14%, 2.89%, 3.43%, 4.06% and 3.62% respectively.	Preprocessing methods, several single models and optimization algorithms are used. Different denoising strategies and optimization methods are compared.	Uncertain predictions and the influence of parameters on model performance are not discussed. The operation time of models is ignored.					
Shao et al. [29]	2021	1. CEEMDAN 2. BPNN+GRNN+RBF+ ELM 3. MOGWO	Several experiments verify the effectiveness of the proposed model with the smallest MAPE value of 2.03%.	The same optimization algorithm is used. Different denoising strategies and optimization methods are compared.	Uncertain predictions and the influence of model parameters are not discussed. The operation time of models is ignored. Lack comparison with other literatures.					
Liu et al. [23]	2019	1. ICEEMDAN 2. BPNN+GRNN+ENN+ELM +ARIMA 3. MMODA	The proposed model can improve the prediction accuracy. MAPE values of multi-step prediction are 3.15%, 4.41% and 5.02% respectively.	The same denoising strategy is applied. Multiple single models are applied. Different denoising strategies and optimization methods are compared.	The optimization algorithm is improved. Wind speed forecasts for different seasons are discussed. The result of parameter adjustment is not discussed in detail.

## Data availability

Because of the sensitive issues involved in the survey, the data would not be shared.

## Declaration of Competing Interest

The authors declare that they have no known competing financial interests or personal relationships that could have appeared to influence the work reported in this paper.

## Acknowledgements

This work was supported by the National Natural Science Foundation of China (Grant No. 71671029).

## Appendix

**Table A** List of terminologies

<b>NWP</b>	numerical weather prediction	<b>GPR</b>	gaussian process regression
<b>ARIMA</b>	autoregressive integrated moving average	<b>ARMA</b>	autoregressive moving average
<b>AI</b>	artificial intelligence	<b>PSO</b>	particle swarm optimization
<b>ANFIS</b>	adaptive neuro-fuzzy inference system	<b>EEMD</b>	ensemble empirical mode decomposition
<b>SSA</b>	singular spectrum analysis	<b>WA</b>	wavelet transform
<b>GM</b>	gray prediction model	<b>CFM</b>	combined forecasting model
<b>CEE</b>	complete ensemble empirical mode decomposition with adaptive noise	<b>ICE</b>	improved complete ensemble empirical mode decomposition with adaptive noise
<b>MOGWO</b>	multi objective grey wolf optimizer	<b>PP</b>	point prediction
<b>IP</b>	interval prediction	<b>AR</b>	autoregressive model
<b>ANN</b>	artificial neural networks	<b>SVM</b>	support vector machines
<b>LSTM</b>	long short-term memory	<b>CNN</b>	convolutional neural network
<b>BPNN</b>	back propagation neural network	<b>ELM</b>	extreme learning machine
<b>GRNN</b>	general regression neural network	<b>ENN</b>	elman neural network
<b>SEM</b>	selection of excellent sub models	<b>AWD</b>	cumulative breadth error
<b>RMSE</b>	root mean square error	<b>MAE</b>	mean absolute error
<b>MAPE</b>	mean absolute percentage error	<b>R<sup>2</sup></b>	goodness of fit
<b>IA</b>	index of agreement of predictive results	<b>RE</b>	relative error
<b>FICP</b>	forecasting interval coverage probability	<b>FINAW</b>	prediction interval standardized mean breadth
<b>MOGOA</b>	multi-objective grasshopper optimization algorithm	<b>MOALO</b>	multi-objective antlion algorithm
<b>MODA</b>	multi-objective dragonfly algorithm	<b>EMD</b>	empirical mode decomposition
<b>GRU</b>	gated recurrent unit	<b>TCN</b>	temporal convolutional networks
<b>QRNN</b>	quasi-recurrent neural networks	<b>RNN</b>	recurrent neural network
<b>WNN</b>	wavelet neural network	<b>VMD</b>	variational mode decomposition
<b>RBF</b>	radial basis function	<b>PSR</b>	phase-space reconstruction
<b>MOMVO</b>	multi objective multi verse optimization	<b>RVFL</b>	random vector functional link network
<b>WOA</b>	whale optimization algorithm	<b>EPT</b>	ensemble patch transformation
<b>SVR</b>	support vector regression	<b>MSSA</b>	multi objective salp swarm algorithm
