## ABSTRACT

**Objective:** To investigate the ability of high density lipoproteins (HDLs) to up-regulate genes with the potential to protect against inflammation in endothelial cells.

**Methods and Results:** Human coronary artery endothelial cells (HCAECs) were exposed to reconstituted HDLs (rHDLs) for 16 hours before being activated with tumor necrosis factor- $\alpha$  (TNF- $\alpha$ ) for 5 hours. rHDLs decreased vascular cell adhesion molecule-1 (VCAM-1) promoter activity by 75% ( $P<0.05$ ), via the nuclear factor-kappa B (NF- $\kappa$ B) binding site. rHDLs suppressed the canonical NF- $\kappa$ B pathway and decreased many NF- $\kappa$ B target genes. Suppression of NF- $\kappa$ B and VCAM-1 expression by rHDLs or native HDLs was dependent on an increase in 3 $\beta$ -hydroxysteroid- $\Delta$ 24 reductase (DHCR24) levels ( $P<0.05$ ). The effect of HDLs on DHCR24 is dependent on SR-BI but not ABCA1 or ABCG1. Silencing DHCR24 expression increased NF- $\kappa$ B (1.2-fold,  $P<0.05$ ), VCAM-1 (30-fold,  $P<0.05$ ) and NF- $\kappa$ B p50 (4-fold,  $P<0.05$ ) and p65 subunits (150-fold,  $P<0.05$ ). TNF- $\alpha$  activation of siDHCR24-treated cells increased expression of VCAM-1 (550-fold,  $P<0.001$ ) and NF- $\kappa$ B (9-fold,  $P<0.001$ ) that could no longer be suppressed by rHDLs.

**Conclusions:** Results suggest that anti-inflammatory effects of rHDLs are mediated partly through an up-regulation of DHCR24. These findings raise the possibility of considering DHCR24 as a target for therapeutic modulation.

### **Condensed Abstract**

This study investigates the ability of high density lipoproteins (HDLs) to up-regulate genes with the potential to protect against inflammation in endothelial cells. The results suggest that the effects of rHDLs are mediated through an up-regulation of  $3\beta$ -hydroxysteroid- $\Delta$ 24 reductase (DHCR24) that functioned as a negative regulator of nuclear factor-kappa B.

**Key Words**

atherosclerosis, endothelial cell, inflammation, nuclear factor-kappa B, 3 $\beta$ -

hydroxysteroid- $\Delta$ 24 reductase

High density lipoproteins (HDLs) have multiple cardio-protective properties. The best known relates to their ability to promote efflux of cholesterol from macrophages (1).

They also inhibit endothelial inflammation (2-5).

HDLs inhibit expression of vascular cell adhesion molecule-1 (VCAM-1), intercellular adhesion molecule-1 (ICAM-1) and E-selectin both *in vitro* (4-6) and *in vivo* (3,7,8) in a process that may be secondary to a suppression of NF- $\kappa$ B activity (4,5,9). We now provide evidence that an HDL-mediated inhibition of VCAM-1 in activated endothelial cells is via blockade of signaling through the classical NF- $\kappa$ B pathway.

Anti-inflammatory effects of HDLs are apparent with both native HDLs and discoidal reconstituted HDLs (rHDLs) that contain only apolipoprotein A-I (apoA-I) and phosphatidylcholine (6,10). Furthermore, the ability of rHDLs to inhibit VCAM-1 expression in TNF $\alpha$ -activated human umbilical vein endothelial cells (HUVECs) persists even if the rHDLs are removed from the culture medium several hours before the cells are activated by TNF $\alpha$  (11).

A similar phenomenon also occurs *in vivo*. Insertion of a non-occlusive collar around a carotid artery of normal-fed rabbits induces expression of VCAM-1 and ICAM-1 in the endothelium and the infiltration of neutrophils into the artery wall. Intravenous infusions of a small amount of rHDLs suppress both the infiltration of neutrophils and the expression of endothelial VCAM-1 and ICAM-1 (7). This anti-inflammatory effect of rHDLs persists even if rHDLs are given 24 hours before applying the inflammatory insult at which time virtually all of the injected rHDLs have been removed from the circulation (8).

On the basis of these findings, we speculated that exposure of endothelial cells to rHDLs induces expression of a protein with the potential to protect against a subsequent inflammatory insult. We now show that incubation of human coronary artery endothelial cells (HCAECs) with either rHDLs or native HDLs induces expression of the anti-oxidant protein,  $3\beta$ -hydroxysteroid- $\Delta 24$  reductase (also known as 24-dehydrocholesterol reductase - DHCR24) in an SR-BI dependent manner. Furthermore, we show that silencing DHCR24 expression increases NF- $\kappa$ B and VCAM-1 levels in both non-activated and TNF $\alpha$ -activated HCAECs with an associated loss of the anti-inflammatory effects of rHDLs.

## **METHODS**

### **Preparation of reconstituted high density lipoproteins**

ApoA-I was purified from human plasma by sequential ultracentrifugation (Beckman Coulter, Fullarton, CA, USA), delipidation and anion-exchange chromatography as previously described (12). Discoidal rHDLs containing apoA-I as their sole protein constituent and 1-palmitoyl-2-linoleoyl-sn-glycero-3-phosphatidylcholine (PLPC, Avanti Polar Lipids, Alabaster, AL, USA) as their sole lipid were prepared by the cholate dialysis method (13).

### **Preparation of high density lipoproteins from rabbit and human plasma**

Twenty New Zealand White rabbits (Institute of Medical and Veterinary Sciences, Adelaide, South Australia) were randomly assigned to experimental groups. Procedures were approved by the Sydney South West Area Health Services Animal Welfare Committee. Chronic arterial inflammation was induced by 6 weeks of feeding a diet containing 0.2% cholesterol-enriched chow. Animals were given intravenous infusions (1ml/min via a catherized ear vein) of either saline or rHDL containing 25 mg of apoA-I (8mg/kg) on days 3 and 5 of the final week of the study. At the end of the 6-week study, blood was collected via cardiac puncture in tubes containing disodium EDTA and placed immediately on ice before animals were euthanized.

Human and rabbits HDLs were isolated by sequential ultracentrifugation (see Supplementary Methods).

### **Cell Culture**

Human coronary artery endothelial cells (HCAECs, Cell Applications, San Diego, CA, USA) were cultured in HCAEC growth medium (Cell Applications). Unless otherwise stated, HCAEC were incubated for 16 hours with rHDLs, native human HDLs (1 mg/ml) or rabbit HDLs (32 µmols/L final apoA-I concentration), or PBS (vehicle control), then stimulated with or without TNF $\alpha$  (0.1 ng/ml) for 5 hours at 37°C in a 5% CO<sub>2</sub> incubator. For the time course experiment, cells were seeded in a 12-well plate at a cell density of 1X10<sup>5</sup> cells/ml (1 ml per well) and pre-incubated with rHDLs (apoA-I 16 µmols/L) or PBS for 0, 1, 2, 4, 8, 12 or 16 hours. The media was then removed, cells washed twice with 500 µl PBS and fresh media added. At 0, 4, 8, 24, 72 or 120 hours post rHDL exposure, total RNA was isolated using TRI reagent (Sigma-Aldrich).

Cells were also incubated with 0.5 µM simvastatin (Sigma-Aldrich, Castle Hill, NSW, Australia) or 54 µM cyclodextrin (Sigma-Aldrich) for 16 hours before isolating RNA.

### **Transient Cell Transfections and Luciferase Measurements**

HCAECs (1X10<sup>5</sup> cells/well of a 12-well plate) were transfected using Effectene (Qiagen, Hilden, Germany) with one of the following plasmids: I $\kappa$ B $\alpha$ -EGFP reporter vector (Clontech Laboratories, Mountain View, CA, USA), NF-κB-luciferase reporter vector (Promega Corporation, Madison, WI, USA) or VCAM-1 promoter-luciferase reporter vectors (14). Luciferase activity was assayed using the Dual-Luciferase Reporter System (Promega). I $\kappa$ B $\alpha$  levels were measured by flow cytometry in a Cytomics FC 500 flow cytometer (Beckman Coulter) using CXP software (Beckman Coulter).

For silencing experiments, HCAECs were transfected with DHCR24 siRNA (Santa Cruz Biotechnology, Santa Cruz, CA, USA), siABCAI, siABCGI or SR-BI siRNAs (Qiagen). See Supplementary Methods.

### **I<sub>K</sub>B Kinase (IKK) Assay**

HCAECs ( $1 \times 10^5$  cells/12-well plate) were pre-treated with rHDLs or PBS for 16 hours, then stimulated with TNF $\alpha$  for 7.5 mins. IKK activity was measured using IKK substrate peptide (Millipore, Billerica, MA, USA) and Kinase-Glo reagent (50  $\mu$ l, Promega, Supplementary Methods).

### **Human NF- $\kappa$ B Target Gene Array Analysis**

The TransSignal NF- $\kappa$ B Target Gene array was used to measure human NF $\kappa$ B target gene expression (Panomics, Princeton, NJ, USA, see Supplementary Method).

### **Real-time PCR**

Total RNA extracted from HCAECs using TRI reagent (Sigma-Aldrich) was normalized to a concentration of 100 ng/ $\mu$ l using the SYBR Green II assay (Molecular Probes, Invitrogen, Melbourne, Australia) and iSCRIPT/ iQ SYBR Green Supermix used to perform RT-PCR in a BioRad iQ5 thermocycler. Relative changes in mRNA levels were determined by the  $\Delta\Delta CT$  method (15), using  $\beta$ 2-microglobulin and 18S levels as controls. Primer pair sequences are included in the Supplement Table I.

### **Affymetrix Human Genome Microarray**

Total RNA (10 µg) was extracted using TRI reagent (Sigma-Aldrich). RNA integrity was determined using an Experion RNA analyzer (BioRad). Samples were then sent to the Australian Genome Research Facility (AGRF; Melbourne, Australia). Microarray image acquisition and differentiated gene analysis were completed using Partek Genomics Suite software (Partek Incorporated, St Louis, Missouri, USA).

### **Western Blot Analysis**

Protein extracts were subjected to Western blot analysis and probed with a goat polyclonal anti-human DHCR24 antibody (Santa Cruz Biotechnology; 1:1000 dilution) and the mouse monoclonal anti-human β-actin antibody (Chemicon, Temecula, CA, USA; 1:10 000 dilution). Direct chemiluminescence imaging of the blots was performed using the ChemiDoc XRS (BioRad) imaging system. Quantity One software (BioRad) was used to quantify band densities.

### **NF-κB Nuclear Translocation Assay**

Nuclear extracts were extracted from HCAECs using the NucBuster protein extraction kit (Merck & Co., Whitehouse Station, NJ, USA). The NF-κB NoShift transcription factor assay kit was used to measure NF-κB levels (Merck & Co.).

### **Statistical Analysis**

Data are expressed as mean ± SEM. Significant differences in treatments were determined by one-way ANOVA with Bonferroni's post-test analysis used to determine significance. Significance was set at  $P<0.05$ .

## RESULTS

### **Role of NF-κB in the anti-inflammatory properties of rHDLs**

To determine the role of NF-κB in the rHDL-mediated suppression of VCAM-1 in activated HCAECs, we studied the VCAM-1 promoter that is controlled mainly by three nuclear factors, activator protein-1 (AP-1), GATA, and NF-κB (16). Nuclear levels of AP-1 and NF-κB both increase in response to TNF $\alpha$  (17) and both are involved in TNF $\alpha$  stimulation of VCAM-1 expression (18). To test the possibility that effects on AP-1 and NF-κB may contribute to the ability of rHDLs to inhibit TNF $\alpha$ -induced VCAM-1 expression, a full-length VCAM-1 promoter DNA fragment (pFFLVCAM-1) and also a shorter fragment of the VCAM-1 promoter DNA that retained the NF-κB sites but not the AP-1 binding site (pF2VCAM-1) were generated by PCR and sub-cloned into the pGL3-luciferase reporter vector (Figure 1A). Transfected HCAECs were exposed to rHDLs for 16 hours before being activated with TNF $\alpha$ . Promoter activity of both FFLVCAM-1 and F2VCAM-1 were significantly inhibited by rHDLs ( $P<0.005$ ) (Figure 1A) indicating that effects on the NF-κB sites fully explain the ability of rHDLs to inhibit VCAM-1 expression in activated endothelial cells.

### **Effect of rHDLs on signalling through the IKK/I $\kappa$ B $\alpha$ /NF-κB pathway**

Prior exposure of HCAECs to rHDLs suppressed the TNF $\alpha$  induced IKK activity ( $P<0.05$ ) (Figure 1B). To determine the effect on I $\kappa$ B $\alpha$  levels and NF-κB activity, HCAECs were transfected with an I $\kappa$ B $\alpha$ -EGFP reporter vector or a NF-κB-luciferase reporter vector. Exposure of the transfected cells to rHDLs increased I $\kappa$ B $\alpha$  levels

(Figure 1C) and suppressed NF-κB mediated DNA transcription as measured by a decrease in luciferase activity (Figure 1D).

### **Effect of rHDLs on TNFα-stimulated NF-κB target gene expression in HCAECs**

To investigate effects of rHDLs on the expression of all NF-κB target genes, HCAECs were exposed to rHDLs or PBS for 16 hours before being activated with TNFα for 5 hours. Exposure to rHDLs suppressed a range of NF-κB-regulated genes (as assessed by macroarray) (Figure 2A), including those belonging to the cell adhesion molecule (CAMs) and metalloproteinase families (Figure 2B), the cytokine and growth factor families (Figure 2C), genes involved in cell cycle regulation (Figure 2D) and AGER, DDH1, HMG14, PRG1 and LAMB2 (Figure 2E). Real-time PCR verified the findings for a selection of genes (Supplementary Table II).

### **Effect of rHDLs on DHCR24 expression in HCAECs**

The above experiments suggest that preincubation of HCAECs with rHDLs induced changes in gene expression so as to make them resistant to subsequent inflammatory insult. To investigate this, HCAECs were incubated with rHDLs (apoA-I 16 μmols/L) or PBS for 16 hours before measuring mRNA levels by Affymetrix human genome U133 Plus 2.0 arrays (54 675 probe sets). The relative expression levels of the differentially expressed genes are shown in the online supplement “Gene List” (Supplementary Table III) at <http://atvb.ahajournals.org>. The top differentially expressed genes are shown in Table 1. All of the differentially expressed genes were filtered by Ingenuity Pathway Analysis database (<http://www.ingenuity.com>). This analysis showed that regulated genes functioned in cholesterol metabolism, inflammation and/or oxidative stress (Supplementary Figure I) including 25

antioxidant proteins or regulators of antioxidants proteins (Supplementary Figure II).

One gene, DHCR24, was highlighted in the top 10 gene list (3<sup>rd</sup> most up-regulated

gene Table 1) and clustered in the cholesterol synthesis biosynthesis pathway

(Supplementary Figure I). DHCR24 catalyses the final step in the cholesterol

biosynthesis pathway, desmosterol to cholesterol. DHCR24 is also a potent H<sub>2</sub>O<sub>2</sub>

scavenger and has antioxidant (19) and anti-apoptotic effects in neuronal cells (20).

Real-time PCR and Western blot analysis confirmed that rHDLs increased DHCR24

mRNA levels by 8-fold (Figure 3A) and protein levels by ~2-fold (Figure 3B). The

difference in expression level measured for mRNA and protein most probably reflects

the increased sensitivity of real-time PCR versus antibody-based chemiluminescence-

dependent Western blot analysis. The rHDL-induced increase in DHCR24 mRNA

levels persisted even in the presence of TNF $\alpha$  (Figure 3A).

We also demonstrated the ability of native HDLs isolated from both human and rabbit

plasma (Figure 3C) to increase DHCR24 expression. In contrast, human LDLs had no

effect on DHCR24 expression (Figure 3C).

rHDLs increased DHCR24 expression in a dose-dependent manner (Figure 3D), with

effects apparent at apoA-I levels as low as 8  $\mu$ mol/L.

In previous studies, we reported that rHDLs inhibited VCAM-1 expression in

activated endothelial cells even if the rHDLs had been removed before activation with

TNF $\alpha$  (11). This was also true for DHCR24 expression. HCAECs required at least an

8 hour exposure to rHDLs to induce DHCR24 expression (Figure 3E). However, once

induced, the effect persisted for at least 8 hours even after the rHDLs had been

removed with DHCR24 expression returning to the un-induced state by 24 hours

(Figure 3F).

### **Effects of DHCR24 on VCAM-1 expression and NF-κB activity**

To determine whether DHCR24 is involved in the ability of rHDLs to suppress inflammatory gene expression in HCAECs, cells were transfected with siRNA targeted against DHCR24. siRNA decreased DHCR24 mRNA levels by about 70% (data not shown) which was associated with a 30-fold increase in VCAM-1 expression ( $P<0.05$ , Figure IIIA Supplementary). When DHCR24-silenced HCAECs were treated with TNF $\alpha$ , VCAM-1 expression was increased 550-fold compared with levels in non-activated cells. In contrast to the control cells, rHDLs did not significantly suppress VCAM-1 expression in TNF $\alpha$  activated DHCR24-silenced cells. DHCR24-silenced HCAECs also showed increased expression of the NF-κB subunits, p50 (4-fold,  $P<0.05$ , Figure IIIB Supplementary) and p65 (50-fold,  $P<0.05$ , Supplementary Figure IIIC) and a 25% ( $P <0.05$ ) increase in NF-κB activity, relative to controls (data not shown).

To determine whether these effects of HDLs on DHCR24 were related to cell cholesterol synthesis or efflux, we treated HCAECs with cyclodextrin to promote cholesterol efflux or simvastatin to block cholesterol synthesis. Cyclodextrin had no effect on DHCR24 or VCAM-1 expression (Figure 4A). Predictably, simvastatin decreased DHCR24 but this was not associated with an increase in VCAM-1 expression, suggesting that inhibition of cholesterol synthesis was not responsible for the elevated VCAM-1 expression in silenced-DHCR24 cells. In keeping with the cyclodextrin result, we found that lipid-free AI had no effect on DHCR24 or VCAM-1 expression (Figure 4B). Furthermore, silencing ABCAI also had no effect on DHCR24 expression or on the ability of rHDLs to increase DHCR24 expression. Similarly, silencing ABCGI had no effect on DHCR24 expression. Silencing SR-BI,

however, did reduce DHCR24 levels both in the presence and absence of rHDLs suggesting that SR-BI is involved in the ability of rHDLs to increase DHCR24 expression (Figure 4C). Together, this final series of experiments suggested that cholesterol synthesis/efflux is not involved in the regulation of DHCR24 by HDLs or in the effects of DHCR24 in HCAECs.

## DISCUSSION

This study demonstrates that rHDL-mediated suppression of NF- $\kappa$ B activity in activated endothelial cells (4,5,11) is achieved via the classical IKK/I $\kappa$ B $\alpha$ /NF- $\kappa$ B signaling pathway, with rHDLs suppressing IKK, increasing I $\kappa$ B $\alpha$  levels, thereby suppressing NF- $\kappa$ B nuclear translocation. Furthermore, suppression of NF- $\kappa$ B activity by rHDLs explains the ability of rHDLs to inhibit VCAM-1 expression and monocyte adhesion to activated endothelial cells. The ability of rHDLs to inhibit many NF- $\kappa$ B target genes may also explain both the known anti-inflammatory and anti-apoptotic properties of rHDLs.

The most striking finding of this study is the ability of both native and reconstituted HDLs to increase endothelial cell expression of DHCR24, an effect that persisted for at least 8 hours after the HDLs had been removed from the culture media. Together, these findings provide an insight into the previously unexplained observation that the response of endothelial cells to an inflammatory insult is markedly reduced by prior exposure to rHDLs even if the rHDLs are removed several hours prior to initiation of the inflammatory insult (11). It may also explain why rabbits injected intravenously with rHDLs 24 hours prior to inserting a non-occlusive silastic collar around the carotid artery remain protected against the resulting acute vascular inflammation, even though the injected rHDLs have long since been cleared from the plasma (9).

DHCR24 catalyses the final step in cholesterol biosynthesis, the conversion from desmosterol to cholesterol (21). However, in addition, DHCR24 is anti-apoptotic and has been shown to regulate cell growth and senescence via an interaction with p53 (20,22). The anti-apoptotic effects may relate to the ability of DHCR24 to scavenge

hydrogen peroxide (19). Since NF- $\kappa$ B is redox sensitive, it is possible that these antioxidant properties suppress both endothelial cell NF- $\kappa$ B activity and the downstream expression of VCAM-1. This possibility is supported by finding that NF- $\kappa$ B activity and VCAM-1 expression were both increased in endothelial cells in which the gene for DHCR24 had been silenced (Supplementary Figure III). Since silencing DHCR24 may have reduced cell cholesterol synthesis and since incubation with rHDLs would have increased cholesterol efflux, it was necessary to determine whether any of the effects observed in these studies were secondary to changes in cellular cholesterol. This possibility was excluded by finding that neither simvastatin nor cyclodextrin had any effect on either DHCR24 or VCAM-1 (Supplementary Figure III). Rather, it was apparent that rHDLs increased the expression of a number of genes functionally associated with the oxidative stress response, including a number of antioxidant proteins, independent of cholesterol metabolism. Interestingly, the most down-regulated gene by HDLs in HCAECs was thioredoxin-interacting protein (TXNIP). TXNIP is an oxidative stress mediator that inhibits thioredoxin (a potent antioxidant) thus the downregulation of TXNIP is in keeping with an augmented antioxidant potential in HCAECs treated with HDLs.

Native as well as reconstituted HDLs increased DHCR24 expression. The observation that lipid-free AI had no effect raises the possibility that phospholipids (rather than apoA-I) may have been responsible for the effect, consistent with previous reports that phospholipid vesicles are as effective as rHDLs in suppressing TNF $\alpha$ -activation of VCAM-1 expression in human endothelial cells (23).

These studies provide a plausible mechanism to explain previous observations that that rHDLs inhibit cytokine-induced cell adhesion molecule expression (4,6,24), metalloproteinase expression (25), apoptosis (26) and thrombus formation (27) in cell and animal models of inflammation. Specifically, we have shown that rHDLs suppress the cytokine-induced expression of many of the NF-κB gene targets, possibly explaining an ability of HDLs to retard plaque progression and/or promote plaque stability. If a reduced expression of DHCR24 were to contribute to development of atherosclerosis, it is possible that an HDL-mediated increase in its expression may limit plaque growth and/or stabilize vulnerable atherosclerotic plaques and reduce their potential to rupture and cause clinical events.

In conclusion, rHDLs have been shown to inhibit VCAM-1 expression in activated endothelial cells via suppression of NF-κB activity. We have also shown that the suppression of NF-κB activity is achieved via blockade of the classical NF-κB signaling pathway rather than through the down-regulation of individual subunit expression of NF-κB per se. This effect of HDL then leads to decreased expression of many NF-κB target genes. And finally, we have shown that rHDLs stimulate endothelial cell expression of DHCR24 in a process that may explain part of the anti-inflammatory properties of HDLs. This involvement of DHCR24 raises the possibility that it should be considered as a future target for therapeutic modulation.

**Table 1: Top regulated genes in HCAECs exposed to rHDLs**

Gene Assignment	p-value	Fold change	Function
SC4MOL // sterol-C4-methyl oxidase-like	0.00058	5.58	Endoplasmic reticulum (ER) protein, cholesterol biosynthesis
HMGCS1 // 3-hydroxy-3-methylglutaryl-Coenzyme A synthase 1	0.0028	4.2	Condenses acetyl-CoA with acetoacetyl-CoA to form HMG-CoA, the substrate for HMG-CoA reductase
DHCR24 // 24-dehydrocholesterol reductase	0.00080	3.68	ER protein, oxidoreductase, cholesterol biosynthesis, antioxidant activities
HMGCR // 3-hydroxy-3-methylglutaryl-Coenzyme A reductase	0.0053	3.60	Multi-pass membrane protein including ER location, rate-limiting enzyme for cholesterol biosynthesis.
ACAT2 // acetyl-Coenzyme A acetyltransferase 2	0.00021	3.49	Multi-pass membrane location including ER, lipid metabolism
FDFT1 // farnesyl-diphosphate farnesyltransferase 1	0.0023	3.34	ER protein, first specific enzyme in cholesterol biosynthesis
SQLE // squalene epoxidase	0.0031	3.33	Multi-pass membrane protein including ER location, catalyses the first oxygenation step in sterol biosynthesis-one of rate-limiting enzymes in pathway
INSIG1 // insulin induced gene 1	0.0035	3.1	ER protein, critical role in regulating cellular cholesterol concentrations
FADS2 // fatty acid desaturase 2	0.00085	2.94	ER protein, catalyzes biosynthesis of HUFA from PUFA, LA and ALA.
DHCR7 // 7-dehydrocholesterol reductase	0.0055	2.73	ER protein, cholesterol biosynthesis
TXNIP // thioredoxin interacting protein	0.0068	-2.84	May act as oxidative stress mediator by inhibiting thioredoxin activity

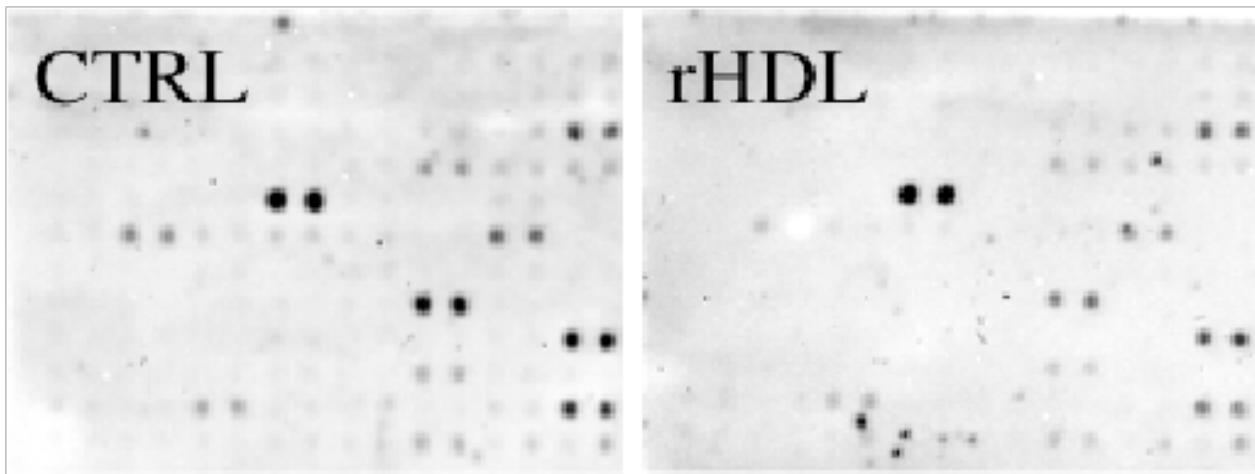

\* ER, endoplasmic reticulum; HUFA, highly unsaturated fatty acids; PUFA, polyunsaturated fatty acids; LA, linoleic acid; ALA, alpha-linolenic

## **Supplementary Experimental Methods**

### **Preparation of high density lipoproteins from rabbit and human plasma**

After collection of blood from rabbits, plasma was isolated by centrifugation at 4°C. The HDL fraction (1.063-1.21g/ml) was isolated by sequential ultracentrifugation and dialysed against phosphate buffered saline (PBS) (1). ApoA-I concentration of the isolated HDLs was determined by immunoturbidometric assay (2). HDLs were added to incubations of endothelial cells at an apoA-I concentration of 32 µmols/L.

HDLs and LDLs were isolated from fresh human plasma containing EDTA by sequential isopycnic ultracentrifugation at the lower and upper density limits of the specified density range. Density adjustments are performed with solid KBr. HDLs and LDLs were washed by centrifugation at the upper density limit to ensure removal of higher density proteins. HDL and LDL are filtered through a 0.45 µM filter and protein concentration quantitated using the BCA assay.

### **IκB Kinase (IKK) Assay**

HCAECs (1X10<sup>5</sup> cells/12-well plate) were pre-treated with rHDLs or PBS for 16 hours, then stimulated with TNFα for 7.5 mins. Cell protein was extracted with buffer containing 1% nonidet P-40, 0.1% sodium dodecyl sulfate (SDS), 0.5% deoxycholate, 150 mM NaCl, 50 mM Tris, pH 8.0 and a protease inhibitor cocktail (Sigma-Aldrich, Castle Hill, NSW, Australia). Protein lysate (10 µg) was incubated with 2 mM ATP and 10 µg IKK substrate peptide (Millipore, Billerica, MA, USA) in reaction buffer (8 mM MOPS, pH 7.0, 0.2 mM EDTA-Na<sub>2</sub>) at room temperature for 90 mins. Kinase-Glo

reagent (50 µl, Promega Corporation, Madison, WI, USA) was added to the reaction mixture, incubated at room temperature for 10 mins and luminescent signal measured on a Fluoroskan Ascent FL (Thermo Labsystems, Waltham, MA, USA).

### **Human NF-κB Target Gene Array Analysis**

Total RNA was isolated from HCAECs using TRI reagent according to the manufacturer's protocol (Sigma-Aldrich). Biotin-labelled cDNA probes were prepared from 10 µg of total RNA from each sample using AMV reverse transcriptase (Promega) and biotin dUTP. The cDNA probes were hybridized to the TranSignal NF-κB Target Gene array following the recommended protocol (Pannomics, Princeton, NJ, USA). Direct chemiluminescence imaging of the membrane was performed using the ChemiDoc XRS (BioRad, Regents Park, NSW, Australia) imaging system. Quantity One software (BioRad) was used for pairwise comparative gene expression after signal intensities were converted to a ratio adjusted for background and housekeeping gene expression. The array reproducibility was evaluated by completing the experiment twice and expression of selected transcripts of interest were confirmed by real-time PCR.

### **Silencing RNA experiments**

To silence DHCR24 expression, HCAECs ( $1 \times 10^5$  cells/12-well plate) were transfected with DHCR24 siRNA (27 pmols, Santa Cruz Biotechnology, Santa Cruz, CA, USA) or Control siRNA-A (27 pmols, Santa Cruz Biotechnology) in siRNA Transfection medium and siRNA Transfection Reagent (Santa Cruz Biotechnology). To silence ABCAI, ABCGI, or SR-BI, HCAECs ( $1 \times 10^5$  cells/12-well plate) were transfected with 100 nM ABCAI, ABCGI, SR-BI siRNA or AllStars negative control (Qiagen, Hilden, Germany)

in a mixture of Opti-MEM (50 uL, Invitrogen, Melbourne, Australia) and HiPerfect (9  $\mu$ L, Qiagen). After a 7-hour incubation, cells were washed with PBS, before adding fresh medium for a further 24 hours. Transfected cells were then incubated with rHDLs or PBS for 16 hours before total RNA was harvested. DHCR24 mRNA levels measured 40 hours after transfection were decreased by up to 70% ( $P<0.05$ , data not shown). Control siRNA-A had no effect on DHCR24 mRNA levels. ABCAI, ABCGI, SR-BI mRNA levels were decreased by up to 80% ( $P<0.0001$ , data not shown), 85% ( $P<0.0001$ , data not shown) and 90% ( $P<0.0001$ , data not shown), respectively.

Relative mRNA levels for selected genes were determined by real-time PCR as described in "Materials and Methods". Primers used to amplify the selected genes were designed using the sequence obtained from the respective gene identifier number listed under the GenBank column. Values are expressed as mean ± SEM relative to PBS controls. Fold difference was determined by the ratio of TNF $\alpha$ +HDL over TNF $\alpha$ . \*  $P < 0.05$ : TNF $\alpha$ +HDL vs TNF $\alpha$ ,  $n = 3$ .

**Figure I**

## Figure II

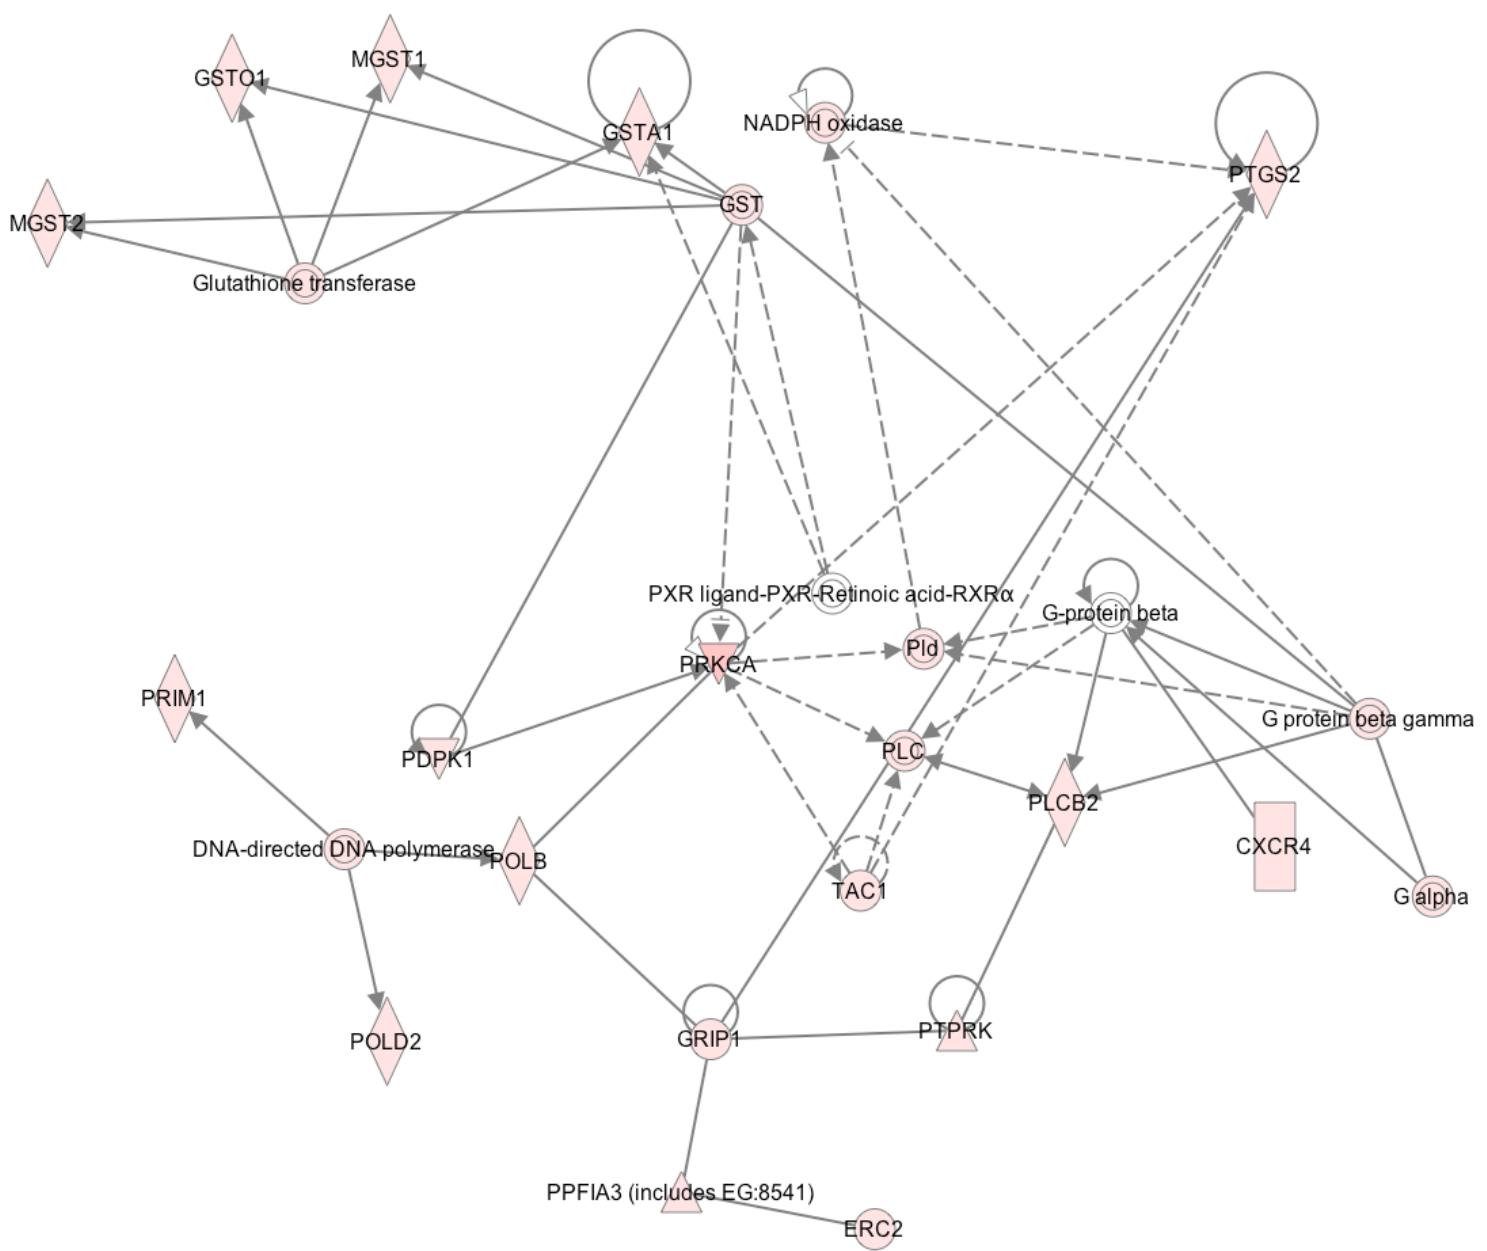

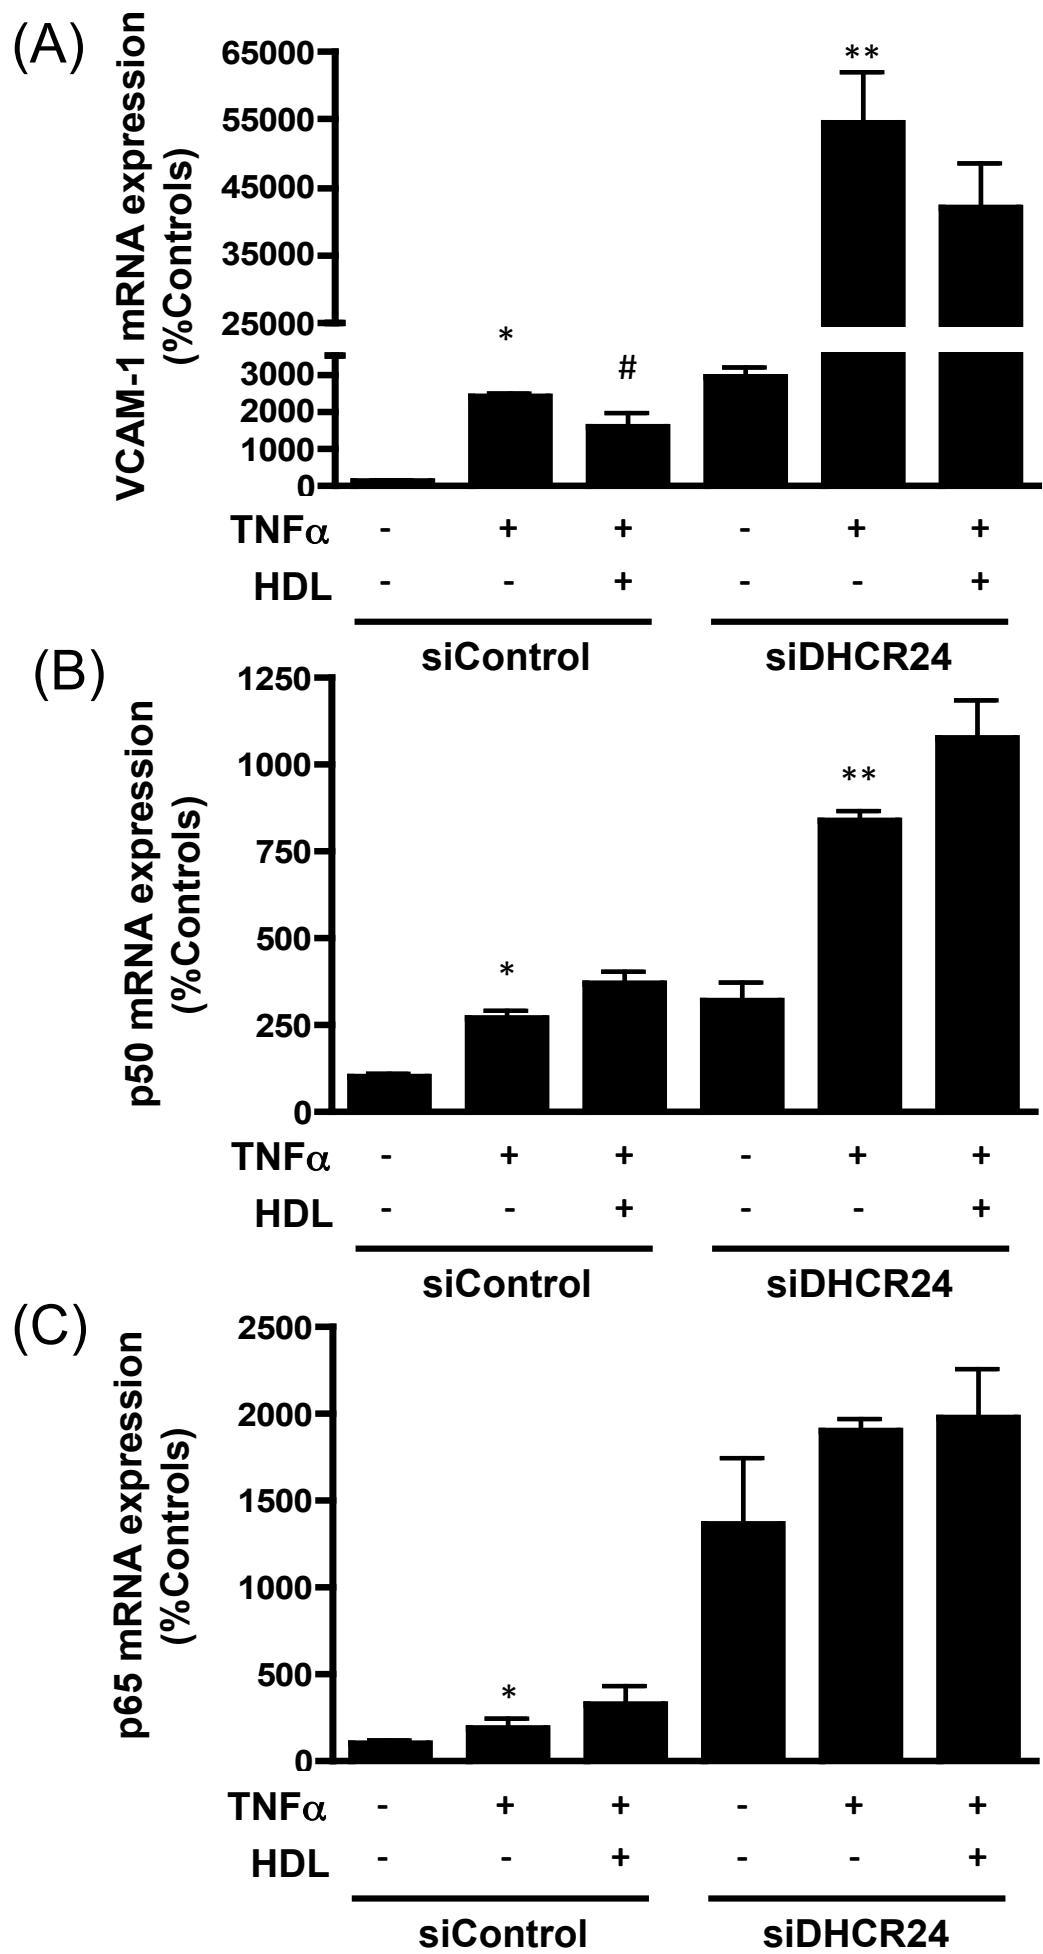

Figure III

## **FIGURE LEGENDS FOR SUPPLEMENTARY MATERIAL**

### **Figure I: Network of functionally related genes regulated by rHDLs.**

Ingenuity Pathway Analysis (IPA) was used to create networks from the comparison rHDL versus PBS ( $P < 0.01$ , ANOVA statistics). The top network produced by IPA is shown. The microarray dataset containing gene identifiers and corresponding expression values was uploaded as an Excel spreadsheet using the template provided in the application. Each gene identifier was mapped to its corresponding gene object in the Ingenuity Pathway Knowledge Base (IPKB). The networks are displayed graphically as nodes (genes/gene products) and edges (the biological relationships between the nodes). A number of the genes in the network are related to cholesterol metabolism/synthesis (marked with green stars), oxidative stress (marked with red stars), apoptosis/cell cycles (marked with blue stars) or inflammation (marked with black stars). The complete list of genes of the networks can be seen in Table II (Supplementary).

### **Figure II: Network of antioxidant related genes regulated by rHDLs.**

IPA was used to create an antioxidant network from the comparison between rHDL and PBS ( $P < 0.01$ , ANOVA statistics). The network is displayed graphically as nodes (genes/gene products) and edges (the biological relationships between the nodes). Shown are a number of genes that are known to be strong antioxidants with their known regulators.

**Figure III: DHCR24 regulates VCAM-1, p50 and p65 NF-κB expression**

HCAECs transfected with siRNA targeted against DHCR24 (siDHCR24) or a scrambled control (siControl) were incubated with rHDLs or PBS for 16 hours with or without activation by TNF $\alpha$  for 5 hours. Total RNA was extracted and subjected to RT-PCR. **(A)** VCAM-1, **(B)** p50 and **(C)** p65 mRNA levels increased in siDHCR24-treated cells with no inhibition by rHDLs. \*P<0.05 compared to PBS-treated controls (siControl). #P<0.05 TNF- $\alpha$  compared to rHDLs+TNF- $\alpha$ . \*\*P<0.05 compared to siDHCR24 PBS-treated controls.
