11 AMR spread via *A. baumannii* plasmids

12 **KEYWORDS**

13 *Acinetobacter baumannii*, antimicrobial resistance gene, AMR, plasmid, plasmid replication,

14 Rep, *rep*, sequence type, and carbapenem resistance

15 ABSTRACT

16 *Acinetobacter baumannii* is a Gram-negative pathogen responsible for hospital-acquired
17 infections with high levels of antimicrobial resistance (AMR). The spread of multidrug-
18 resistant *A. baumannii* strains, particularly those resistant to carbapenems, has become a global
19 concern. Spread of AMR in *A. baumannii* is primarily mediated by the acquisition of AMR
20 genes through mobile genetic elements, such as plasmids. Thus, a comprehensive
21 understanding of the role of different plasmid types in disseminating AMR genes is essential.
22 In this study, we analysed the distribution of plasmid types, sampling sources, geographic
23 locations, and AMR genes carried on *A. baumannii* plasmids. A collection of 814 complete
24 plasmid entries was collated and analysed. Most plasmids were identified in clinical isolates
25 from East Asia, North America, South Asia, West Europe, and Australia.

26 We previously devised an *Acinetobacter* Plasmid Typing (APT) scheme where *rep/Rep* types
27 were defined using 95% nucleotide identity and updated the scheme in this study by adding 13
28 novel *rep/Rep* types (93 types total). The APT scheme now includes 178 *Rep* variants
29 belonging to three families: R1, R3, and RP. R1-type plasmids were mainly associated with
30 global clone 1 strains, while R3-type plasmids were highly diverse and carried a variety of
31 AMR determinants including carbapenem, aminoglycoside and colistin resistance genes.
32 Similarly, RP-type and *rep*-less plasmids were also identified as important carriers of
33 aminoglycoside and carbapenem resistance genes. This study provides a comprehensive
34 overview of the distribution and characteristics of *A. baumannii* plasmids, shedding light on
35 their role in the dissemination of AMR genes. The updated APT scheme and novel findings
36 enhance our understanding of the molecular epidemiology of *A. baumannii* and provide
37 valuable insights for surveillance and control strategies.

38 **IMPORTANCE**

39 *A. baumannii* has emerged as a major cause of nosocomial infections, particularly in intensive
40 care units, posing a substantial challenge to patient safety and healthcare systems. Plasmids,
41 which carry antimicrobial resistance (AMR) genes, play a crucial role in the multidrug
42 resistance exhibited by *A. baumannii* strains, necessitating a comprehensive understanding of
43 plasmid spread, and how to track them. This study provides important insights into *A.*
44 *baumannii* plasmid epidemiology, and the extent of their role in spreading clinically significant
45 AMR genes and how they are differentially distributed across different clones i.e. sequence
46 types (STs) and geographical regions. These insights are important for identifying high-risk
47 areas or clones implicated in plasmid transmission, in the context of the spread of multidrug-
48 resistant *A. baumannii* strains. It also highlights the involvement of R3-type, RP-type and rep-
49 less plasmids in the acquisition and spread of significant AMR genes including those conferring
50 resistance to carbapenems, aminoglycosides and colistin.

51 INTRODUCTION

52 *Acinetobacter baumannii* is a notorious opportunistic Gram-negative pathogen that causes
53 hospital-acquired infections, such as bacteraemia, pneumonia, wound infections and urinary
54 tract infections ¹ that are difficult — and in many cases impossible — to treat due to high levels
55 of resistance to several antimicrobial classes ^{2,3}. Indeed, the spread of *A. baumannii* strains
56 resistant to all available antimicrobials has become a major global concern ^{3,4}, and carbapenem-
57 resistant *A. baumannii* has been flagged by the World Health Organisation as the number one
58 priority for antimicrobial development ⁵. In *A. baumannii*, antimicrobial resistance (AMR) is
59 known to occur primarily by the horizontal acquisition of AMR genes via mobile genetic
60 elements (MGEs) such as transposons and plasmids ^{3,6-8}. Notably, *A. baumannii* plasmids are
61 increasingly recognised as a major source for disseminating AMR genes such as those that
62 confer resistance to carbapenems and colistin ⁹⁻¹³.

63 *A. baumannii* has a unique repertoire of plasmids that capture and mobilise a wide range
64 of genetic material involved in pathogenesis and AMR (6, 15-18). Recently, we developed a
65 plasmid typing scheme based on the sequence of replication initiation genes from 621 complete
66 *A. baumannii* plasmids called *Acinetobacter* Plasmid Typing (APT) scheme ¹³. This first
67 version of the APT scheme includes 80 Rep types belonging to three families; R1 types 1 to 6,
68 R3 types 1 to 69, and RP types 1-5
69 (<https://github.com/MehradHamidian/AcinetobacterPlasmidTyping>) ¹³. However, the role of
70 each plasmid type in dissemination of AMR genes remains to be established. To date, several
71 studies have examined the role of *A. baumannii* plasmids in the spread of AMR genes ^{9,10,14-17}
72 but most of these studies have only reported on individual or a limited number of plasmids and
73 thus, a comprehensive overview of how various plasmid types are involved in the
74 dissemination of AMR genes remains elusive. In this study, we address this gap by examining

75 the distribution of chromosomal sequence types, sampling, geographies, and AMR genes
76 carried on plasmids originally included in the APT database alongside an additional 193
77 complete plasmids that have since been deposited in GenBank (as of August 18, 2022). We also
78 provide an update to the original APT scheme with the addition of novel *rep*/Rep types.

79 **RESULTS AND DISCUSSION**

80 **Overview of genome and plasmid dataset.** As of August 18, 2022, 450 complete *A.*
81 *baumannii* genomes were available in GenBank. Of these 450 complete genomes, 80% (n=355)
82 had at least one plasmid (Table S1) with 236 genomes containing one (n=1) plasmid, and 113
83 carrying two plasmids (Table 1 and Table S1). Ninety-one (n=95) genomes lacked a plasmid
84 and were not studied here. To broaden our plasmid dataset, we extended our search to the
85 RefSeq database and captured an additional 92 genomes that contained at least one (n=1)
86 plasmids. Of these 92 genomes/unique strains, n=63 were not linked to a genome project and
87 n=29 genomes were sourced from WGS (Whole Genome Shotgun), which included draft
88 genomes with complete plasmid entries. Following curation of the dataset (i.e. exclusion of
89 duplicate entries and assembly QC; see methods for more details), our final dataset was
90 comprised of 814 non-redundant plasmid entries corresponding to at least 440 unique isolates
91 (Table S1 and Table S2; n=2/814 plasmids unassigned due to absence of BioSample and strain
92 name). Notably, of the 440 unique genomes/isolates, the *rep*/Rep sequences of n=329 were had
93 already been analysed in the original APT scheme¹³. Indeed, in this study, we investigated the
94 prevalence of antimicrobial resistance (AMR) genes within different plasmid types,
95 considering their associated meta-data. A total of 440 unique genomes/strains were analysed,
96 comprising both the 329 genomes previously reported and an additional 111 genomes captured
97 in this study. Over half of the isolates carried one plasmid (n=229 isolates; 52%) and 27%

98 (n=120) carried two plasmids (Table 1). Seven genomes contained 6-11 plasmids, indicating
99 that some *A. baumannii* strains have the capacity to carry a significantly high load of plasmids.

100 Of the 440 unique isolates, ST2 represented the most abundant sequence type (n=199),
101 followed by ST1 (n=25), ST25 (n=14), and ST622 (n=10). In 2019, we reported that both the
102 geographies and sampling types of publicly available *A. baumannii* genomes deposited in
103 NCBI were extremely skewed³. This is similarly reflected in this dataset, with the vast majority
104 sequenced in strains recovered from clinical samples (n=359; 81.5%), and few from non-
105 clinical sources (FIG 1). This is primarily because of continued significance and attention paid
106 towards clinical strains, and a lessened focus on studying the role of non-clinical reservoirs
107 (e.g. environment, animals) as potential sources for plasmids and AMR genes. Most complete
108 plasmid entries were sequenced from isolates collected in East Asia (primarily China,
109 n=105/155 isolates), followed by North America (primarily US, n=77/90) and South Asia
110 (primarily India, n=44/46). The strains were isolated from forty-three countries, and those with
111 at least ten plasmids plus isolates within the dataset included South Korea (n=38), Australia
112 (n=15), France (n=15), Canada (n=13), Iraq (n=12), Mexico (n=12), and Italy (n=10; see FIG
113 1 and Table S1 and Table S2).

114 **Novel *rep* sequences and update to the *Acinetobacter* Plasmid Typing (APT)**
115 **scheme.** Of the 814 plasmids studied here, 621 (i.e. 71%) were previously used to generate
116 the first version of the APT scheme. An additional 193 complete plasmid entries, corresponding
117 to 92 isolates, had since been released in GenBank between February 2021 and mid-August
118 2022. Using the criteria we had previously established for assigning *rep* types (i.e., 95% DNA
119 identity)¹³, n=13 novel *rep* types were identified (n=10 R3 types, designated R3-T70 to R3-
120 T79; n=2 R1 types, R1-T7 and R1-T8; n=1 RP type, RP-T6), resulting in a total of n=78, 7
121 and 6 R3, R1 and RP types, respectively (Table 2, Table S2). In addition to the novel *rep*/Rep

122 sequences, we also report additional updates to the scheme as follows. R3-T49 has been
123 removed from the updated APT scheme, as the corresponding *rep* sequence (previously r3-
124 T49_NZ_AYFZ01000080.1_pABUH2a-5.6_c33) has been identified as a R3-T26 variant.
125 Specifically, this variant carries an insert of 84 bp that differentiates this sequence from the
126 other R3-T26 variants. This entry has been subsequently renamed to R3-T26* and R3-T49
127 retired from the scheme. R1-T3 was also retired due to possible sequencing/assembly errors
128 resulting in shortening the Rep reading frame by approximately 150 amino acids. Lastly, we
129 highlight two corrections to Figure 3 and Table 3 published in the original APT paper ¹³: i) R3-
130 T3 was annotated twice in FIG 3; the first annotated clade highlighted in orange should be
131 corrected to R3-T8, and ii) in Table 3, the rows and columns should read R1-T1 to R1-T6 (i.e.
132 not P1-T1 to P1-T6).

133 **Plasmids encoding the Rep₁ family replication protein (Rep₁ or R1**
134 **plasmids) do not carry AMR genes.** R1-type plasmids (encoding Pfam01446) are often
135 2-3 kb in length and are typically comprised of a replication initiation protein and only two or
136 three additional open reading frames encoding hypothetical proteins. R1-type plasmids
137 constitute a small fraction of the plasmid dataset (n=16 plasmids, 13 isolates) and none of these
138 carried AMR genes, suggesting that these plasmids are not yet involved in the acquisition and
139 spread of AMR. Strains belonging to global clone 2 (GC2; largely represented by ST2)
140 constitute over 90% of all *A. baumannii* genomes in GenBank, but R1 plasmids appear to be
141 mainly associated with strains belonging to global clone 1 (GC1; largely represented by ST1,
142 n=9/13 isolates) with only n=1 GC2 strain found with R1 plasmids (FIG 2).

143 **Rep₃ (R3) plasmids disseminate important AMR genes.** R3 plasmids encoding
144 the Rep₃-type plasmid replication proteins (Pfam01051) represent, by far, the most diverse *A.*

145 *baumannii* plasmid group. This is due to several reasons, including the Rep/*rep* sequence
146 divergence combined with their floating genetic structure arising from the presence of *pdif*
147 modules (examples in FIG 3). Over half of the plasmids were typed as R3 (n=479/814
148 plasmids; 59%), and these were detected in at least 345 unique isolates (note, n=2 R3 type
149 plasmids were unassigned to an isolate). Variants of R3-T1, T2 and T3 constitute the most
150 abundant types and were collectively detected in n=224 plasmids. R3-type plasmids appear to
151 be geographically dispersed, but some types appear to be limited to distinct regions (FIG 4).
152 For example, some variants of R3-T1 plasmids that carry a carbapenemase appear to be limited
153 to North America (e.g. pAB120 carrying *bla*_{OXA-72} from the US; GenBank accession number
154 CP031446.1) or Europe (e.g. p1ABST78 from Italy; GenBank accession number
155 AEOZ01000236.1 (FIG 4, Table S1 and Table S2), and may represent local plasmid circulation
156 or expansions.

157 The updated R3 phylogeny generated from n=145 R3 *rep* nucleotide variants (n=78 distinct
158 *rep* types) revealed two deep-branching clades containing n=61 and 84 *rep* types, with plasmids
159 carrying AMR genes (including carbapenemases) dispersed across both clades. Approximately
160 half of the R3 types were associated with plasmids without AMR (n=36/78 R3 types), while
161 n=18 were linked only to plasmids that carry AMR, and n=24 (including the majority of the
162 top 15 most common R3 types; see FIG 4) were associated with both AMR⁺ and AMR⁻
163 plasmids.

164 A quarter of R3-type plasmids (n=122/479; n=42 distinct R3 types collectively) were
165 associated with AMR, and n=73 of these plasmids (from at least n=72 isolates) carried
166 carbapenemases. Various AMR genes were detected on R3 plasmids; however, the *bla*_{OXA-58},
167 *bla*_{OXA-72}, *bla*_{OXA-24} carbapenem resistance, *tet39* tetracycline resistance, *sul2* sulfonamide
168 resistance and *msr-mph*(E) macrolide resistance genes were amongst the most abundant AMR

169 genes found (Table S2). R3-type plasmids with AMR genes are carried by all major global
170 clones including ST10, ST15, ST25, ST79 and ST85 strains, which collectively accounted for
171 n=26/345 isolates carrying n=46 R3-type plasmids, but were predominantly detected in
172 members of GC2 and GC1, accounting for n=150 and 26 isolates with R3-type plasmids,
173 respectively (n=209/479 R3-type plasmids; see FIG 4 and Table 3).

174 Colistin is a last resort within our arsenal of antibiotics that largely remained effective against
175 multi-drug resistant (MDR) *A. baumannii*¹⁸. Here, the *mcr* colistin resistance gene was present
176 in only n=5 isolates, all of which were linked to R3-type plasmids. These included 4 plasmids
177 with the *mcr-4.3* gene carried by strains recovered in clinical samples (two strains isolated in
178 each of China and the Czech Republic) on an R3-T22 plasmid (Table S2). The remaining
179 plasmid, p8E072658, was recently described in an environmental isolate from recycled fibre
180 pulp in a paper mill in Finland¹⁴. This plasmid carries the novel *mcr-4.7* colistin resistance
181 gene in a Tn3-family transposon and encodes two novel R3-type Reps (R3-T73 and R3-T74).
182 Acquisition of the *mcr* plasmids is clinically significant given the importance of colistin in
183 treatment of MDR *A. baumannii*, and while it currently appears to be uncommon, future
184 monitoring of R3 plasmids with *mcr* may be warranted.

185 **The RP-type plasmids (encoding RepPriCT_1) disseminate aminoglycoside**
186 **and carbapenem resistance genes.** RP-type plasmids encoding RepPriCT_1
187 (Pfam03090) Rep have been reported in various *A. baumannii* strains and contribute to the
188 emergence of MDR strains^{12,19-24}. Approximately one-fifth of the dataset (n=158 plasmids;
189 19.4%) were identified as RP-type. A significant portion of RP-type plasmids (n=64/158;
190 40.5%) carry at least one AMR gene highlighting the importance of this plasmid group in the
191 acquisition and spread of AMR determinants. The majority of RP-type plasmids were typed as
192 RP-T1 followed by RP-T2, accounting for n=130 and 22 plasmids (82.3% and 13.9%)

193 respectively. The genetic structure of the predominant RP-T1 plasmid variant (pACICU2;
194 GenBank accession number CP031382.1), is illustrated in Figure S1.

195 In fact, RP-T1 and RP-T2 plasmids accounted for all AMR⁺ RP-type plasmids. All n=49 RP-
196 T1 AMR⁺ plasmids carried either *bla*_{OXA-23} (carbapenemase; n=31 RP-T1 plasmids) and/or
197 *aphA6* (amikacin resistance; n=30 RP-T1); n=12 RP-T1 plasmids carried both. Other AMR
198 genes detected in the RP-T1 plasmids included *sull1*, *dfrA7*, *aacA4*, *bla*_{GES-11}, *strAB*, *aadA2*,
199 *cmlA1*, *aadB*, and the *bla*_{OXA-58} carbapenemase (FIG 5 and Table S2). Moreover, it appears that
200 variants of RP-T1 plasmids have similarly been acquired by all major globally distributed
201 clones including members of GC1 and GC2, ST10, ST15, ST25, ST79 and ST622, recovered
202 across all continents (FIG 5).

203 In contrast to the global distribution of RP-T1 plasmids, all n=22 RP-T2 plasmids were
204 sequenced from isolates collected in East Asia (predominantly China, except for one plasmid
205 with no AMR genes sequenced from an isolate in South Korea). Notably, n=15/22 plasmids
206 contained a *bla*_{OXA-23} copy suggesting that RP-T2 plasmids with *bla*_{OXA-23} are circulating in
207 China and have not yet been detected elsewhere. Plasmids corresponding to the remaining RP-
208 types were generally small plasmids ranging in size from 4.5kb to 6.8kb (except for RP-T3;
209 52.5 kb) and carry no AMR genes. Interestingly, phylogenetic analysis of RP-type *rep*
210 sequences (RepPriCT_1 family) revealed a clear separation of the smaller plasmids that lack
211 AMR genes (RP-T4, RP-T5 and RP-T6) from the larger RP-T1, T2 and T3 plasmids (Figure
212 X), suggesting distinct evolutionary trajectories that have likely influenced the accumulation
213 of additional genes including those conferring AMR.

214 **Distribution of AMR genes in plasmids with no identifiable replication gene.**

215 We previously reported that a fraction of *A. baumannii* plasmids do not encode an identifiable

216 replication initiation gene (i.e. 22.9%; n=142/621 plasmids)¹³. Such plasmids might therefore
217 use an alternative mechanism that does not involve a Rep to initiate replication or encode a
218 novel Rep that is yet to be discovered. Here, n=161/814 plasmids did not encode an identifiable
219 replication initiation gene. This *rep*-less group constitutes a set of highly diverse plasmids
220 ranging in size from 4 kb to over 200 kb. Almost a third of these (n=52; 32.3%) appear to carry
221 no AMR genes and range in size from 2.4 – 145.7 kb (Table 4). These plasmids are not
222 discussed further as they lack AMR genes. The remaining n=109 plasmids (length range 3.8 kb
223 to >200 kb) carry at least one AMR gene and constitute various plasmid variants. Some variants
224 are associated with the carriage of clinically significant AMR genes, and include those related
225 to pRAY*, large MPFF conjugative plasmids such as pA297-3, and pNDM-BK01 (n=28, 31
226 and 8, respectively; accounting for 41.6% *rep*-less plasmids). These plasmids are further
227 discussed below.

228 **i) pRAY* – an important small plasmid spreading resistance to aminoglycosides.** It has
229 been shown that the small plasmid pRAY* and its variants play a role in the spread of the *aadB*
230 gene conferring resistance to tobramycin, gentamicin and kanamycin, which are considered
231 clinically significant antimicrobials²⁵. Although some variants did not carry an AMR gene (an
232 example shown in FIG 6), we observed n=28 plasmids that were either identical or closely
233 related to pRAY*, and most (n=25/28) carried *aadB*. These plasmids were found in strains
234 assigned to at least 14 STs, including ST1, ST81, ST2, ST25 and ST85 (Table S3). The strains
235 were also geographically diverse, indicating global dissemination of pRAY* plasmids.
236 Moreover, all strains with pRAY* were recovered in clinical samples suggesting
237 aminoglycoside selective pressures may play a role in driving their stable maintenance within
238 clinical settings (Table S3).

239 **ii) Spread of diverse AMR genes by conjugative plasmids encoding the MPF_F transfer**
240 **system.** This group constitutes a diverse set of n=31 large plasmids (146.7 – 236.2 kb in size)
241 known to lack an identifiable *rep* gene. These plasmids were detected in at least 11 distinct STs
242 with the highest count corresponding to ST622 (n=10) followed by ST25 (n=7) and were also
243 present in members of the major global clones (e.g. ST1, ST10, ST25; Table S4). The 200.6 kb
244 plasmid, pA297-3 (Table S4) is considered the representative as it has the most common
245 backbone type and was one of the earliest described and shown to be conjugative ¹¹. It carries
246 *sul2* and *strAB*, conferring resistance to sulphonamide and streptomycin respectively. Most
247 plasmids in this group (except p40288 and pR32_1; Table S4) carry a copy of *sul2*. Most
248 members also carry *strAB* (n=28/31), *msr-mph*(E) (n=21), *bla*_{PER-7} (n=18), and *armA* (n=20)
249 conferring resistance to streptomycin, macrolides, extended-spectrum β -lactamases (ESBLs),
250 and aminoglycosides, respectively (Table S4). The latter, *armA*, encodes the 16S rRNA
251 methylation protein that confers resistance to all aminoglycosides ²⁶. Two plasmids,
252 pPM193665_1 and pPM194122_1 (GenBank accession numbers CP050416 and CP050426,
253 respectively) from strains recovered in India, also contain the *bla*_{NDM} metallo- β -lactam
254 carbapenem resistance gene.

255 **iii) Conjugative plasmids encoding MPF_T transfer system.** Though not very common,
256 *bla*_{NDM} has now been reported in *A. baumannii* in several countries ^{3,27-30}. In this study, we
257 found n=8 plasmids with no identifiable *rep* gene that encode the MPF_T type conjugative
258 transfer system ³¹ and carried the *bla*_{NDM} metallo-beta-lactam carbapenem resistance gene
259 (Table 6). All these plasmids were found to be related to pNDM-BJ01 (GenBank accession
260 number JQ001791.1), which was first reported in *Acinetobacter lowffii* and shown to be
261 conjugative at a high frequency ³². These plasmids were carried by strains recovered in clinical,
262 environmental (wastewater) and animal samples in different countries including China, Japan,

263 US, Colombia, and Brazil showing their wide geographical distribution. They were found in
264 various sequence types, of which only one (p1AR_0088; GenBank accession number
265 CP027532.1; Table S2 and Table S5) was in a ST25 strain, which is an important globally
266 distributed ST ^{3,15,33-35}. Given the potential for accelerated resistance dissemination of
267 resistance to a last-line antimicrobial and hence heightened therapeutic challenges, targeted
268 surveillance of MPF_T type plasmids with *bla*_{NDM} may be warranted.

269 **Diverse plasmid types facilitating the spread of carbapenem resistance genes.**

270 Carbapenemases stand out as important AMR determinants as carbapenems are one of the last
271 resort lines of defence in antimicrobial treatment ³. Here, we showed that various R3, RP and
272 *rep*-less plasmids were associated with the spread of carbapenem resistance genes including
273 *bla*_{OXA-23}, *bla*_{OXA-24}, *bla*_{OXA-58}, and *bla*_{NDM}. Carbapenemases were observed in 150 plasmids
274 (18.4%), of which *bla*_{OXA}-type genes were the most common carbapenemase type followed by
275 *bla*_{NDM} (n=132, 11 and 7 plasmids with *bla*_{OXA} only, *bla*_{NDM} only and *bla*_{OXA} plus *bla*_{NDM}
276 respectively). We detected twelve allelic variants of *bla*_{OXA}-type genes; *bla*_{OXA-23} was the most
277 prevalent (n=54), followed by *bla*_{OXA-58} (n=33, of which n=6 also carried *bla*_{NDM-1}), *bla*_{OXA-72}
278 (n=27), and *bla*_{OXA-24} (n=11). The prevalence of some of these alleles appear to be associated
279 with distinct plasmid types. For example, n=46/54 *bla*_{OXA-23} plasmids were typed as RP-T1 or
280 RP-T2, while R3-type plasmids appear to play a key role in the dissemination of *bla*_{OXA-58} (i.e.
281 n=28/33 plasmids with *bla*_{OXA-58}), *bla*_{OXA-72} (n=21/27), and *bla*_{OXA-24} (n=10/11). Notably,
282 except for *bla*_{OXA-23}, which was abundant in ST2 isolates (n=33/54 *bla*_{OXA-23} plasmids), there
283 was no clear correlation of carbapenemase-carrying plasmids with particular sequence types
284 (ST), indicating widespread distribution of plasmids between various *A. baumannii* clones.

285 The *bla*_{NDM} carbapenem resistance gene is clinically significant in all Gram-negative bacteria,
286 especially Enterobacterales as its rapid spread among different bacterial species worldwide has

287 become a serious threat to public health ³⁶. A single allelic variant, *bla*_{NDM-1}, was observed in
288 this dataset and detected in n=13 plasmids including n=8 pNDM-BJ01-type variants, n=2 R3-
289 type n=2 pA297-3-type, and a novel plasmid pCCBH31258 (GenBank accession number
290 CP101888). The presence of *bla*_{NDM} on conjugative plasmids in *A. baumannii* is significant as
291 it highlights the potential for the rapid transmission of this important carbapenemase via
292 horizontal gene transfer.

293 **Opportunities and limitations.** Advances in whole genome sequencing technologies
294 combined with the rapid accumulation of genome data in publicly available databases such as
295 GenBank has provided a valuable opportunity to gain genomic insights towards the circulation
296 of AMR genes in critical pathogens such as *A. baumannii* and, more importantly, MGEs that
297 disseminate AMR. However, this unique opportunity is associated with important caveats given
298 that publicly available genome sequences are largely geographically skewed for several
299 reasons, including the lack of technology, financial support and expertise in developing
300 countries. Currently, the bulk of genome sequence data in GenBank has been sequenced from
301 isolates collected in the US, China and Australia; these countries accounted for approx. ~50%
302 of the dataset in this study. The geographical skew of genome sequence data makes it difficult
303 to gain comprehensive insights into population structure, MGEs and AMR genes circulating in
304 other parts of the world e.g. Africa and the Middle East. Moreover, genomes of environmental
305 *A. baumannii* strains are also very limited (FIG 1), making it difficult to understand the
306 distribution of AMR genes and MGEs including plasmids in the environment. Consequently,
307 the scarcity of environmental genome data also limits the study of how plasmids, particularly
308 those with AMR, circulate between the strains from clinical and environmental origins.

309 **CONCLUSIONS**

310 Traditionally, *A. baumannii* has been characterized as an organism that primarily acquires AMR
311 genes through large chromosomal islands. However, this definition is changing as more
312 plasmids that carry important AMR genes are being characterised. This study also highlights
313 the pivotal role of various plasmid types, particularly certain families in the dissemination of
314 clinically important AMR genes within this pathogen. We showed that many RP-T1, R3-types
315 (e.g. RP-T1 and R3-T2) and rep-less pNDM plasmids can spread various carbapenem
316 resistance genes. These are of particular concern as AMR genes conferring resistance to
317 carbapenems are often considered as the last line of defence in treatment. Furthermore, these
318 plasmids typically carry additional AMR genes conferring resistance to multiple
319 antimicrobials, which further compounds treatment management and the threat posed by *A.*
320 *baumannii*.

321 Although the plasmid repertoire of *A. baumannii* exhibits remarkable diversity, this
322 investigation highlights the profound significance of specific plasmid families in harboring and
323 disseminating AMR genes. The findings from this study provide new insights into which
324 plasmid types are over-represented among those that disseminate AMR and may be flagged as
325 targets for focused AMR surveillance. Finally, this study showed that, in the ongoing battle
326 against antibiotic resistance in *A. baumannii*, its plasmids play a significant role in exacerbating
327 the crisis. Their ability to transfer AMR genes across different sequence types, coupled with
328 the bacterium's adaptability, poses a formidable challenge to healthcare systems worldwide.

329 **MATERIALS AND METHODS**

330 **Plasmid sequence data.** A local database of complete *A. baumannii* plasmids that were
331 publicly available as of mid-August 2022 was generated. Our local database included plasmid
332 sequences of i) 355 complete genomes out of 450 complete *A. baumannii* genomes (i.e. n=95

333 entries with no plasmids) sourced from GenBank
334 (<https://www.ncbi.nlm.nih.gov/genome/browse#!/prokaryotes/403/>); labelled as ‘Complete
335 genome project’ as data source in Table S1 and Table S2) and ii) an additional 92
336 genomes/unique strains (released between February 2021 and mid-August 2022) captured in
337 RefSeq (<https://www.ncbi.nlm.nih.gov/refseq/>). The latter included n=29 genomes were
338 sourced from Whole Genome Shotgun projects (labelled as ‘WGS’ in Table SX) and n=63
339 unique strains that were not linked to a genome project (i.e. direct plasmid submission to
340 GenBank; labelled as ‘GenBank non-redundant db’ in Table S2). This resulted in the curation
341 of our final dataset consisted of 814 non-redundant plasmid entries corresponding to at least
342 440 unique isolates (n=355 isolates from Complete genome projects, n=63 from GenBank non-
343 redundant database, and n=29 from WGS). Of the 814 plasmid entries, n=621 were those we
344 previously used to develop the *Acinetobacter* Plasmid Typing scheme¹³. All supporting data
345 and protocols have been provided within the article or through supplementary data files. The
346 online version of this article has four supplementary tables and three supplementary figures.

347 **Bioinformatics and sequence analysis.** The chromosomal sequences associated each plasmid
348 were found by exporting the BioSample accession numbers using the RefSeq
349 <https://www.ncbi.nlm.nih.gov/refseq/> followed by the curation of a list of chromosomal
350 GenBank accession numbers and downloading the sequence data through Entrez Programming
351 Utilities (E-utilities; <https://www.ncbi.nlm.nih.gov/books/NBK25501/>). Chromosomal
352 sequences were used to determine the Multi-locus Sequence Types (MLSTs) using the *mlst*
353 v.2.0 software (<https://github.com/tseemann/mlst>). Standalone BLAST
354 (<https://ftp.ncbi.nlm.nih.gov/blast/executables/LATEST/>) was used for plasmid sequence
355 comparisons within the *rep*-less plasmid group and assign ‘related known plasmid’ variants as
356 labelled in Table S2. The SnapGene® (V.6.0.5) software was used to examine the structure of

357 individual plasmids. The plasmids were screen for AMR genes using Abricate v1.0.1 (available
358 at <https://github.com/tseemann/abricate>) using the ResFinder v.2.1 database (available under
359 <https://cge.cbs.dtu.dk/services/ResFinder/>). Data visualisation was performed using the
360 ggplot2 package (<https://ggplot2.tidyverse.org/>) in R (v1.1.456) and Adobe Illustrator
361 (V23.0.3).

362 **Clustering and phylogenetic analysis of the *rep*/Rep sequence data.** *rep*/Rep sequences were
363 extracted from the novel plasmid entries using the SRST2 software ³⁷ followed by manual
364 curation. Clusters comprising *rep* sequences at >95% nucleotide identity were derived using
365 CD-HIT Suite (<https://github.com/weizhongli/cdhit>) ³⁸, as previously described ¹³. The *rep*
366 nucleotide sequences were separately aligned for each of the Rep families using MUSCLE
367 v3.8.31 ³⁹. Phylogenies were generated using the aligned *rep* sequences as input into RAxML
368 v8.2.9 run five times with the generalised time-reversible (GTR) model and a Gamma
369 distribution. The final trees with the highest likelihoods were selected, visualised in FigTree
370 v1.4.4 (<http://tree.bio.ed.ac.uk/>), and annotated with the plotTree code
371 (<https://github.com/katholt/plotTree>) in R v1.1.456.

372 **ACKNOWLEDGEMENTS**

513 ^a Sequence Types of strains that carry plasmids

514 **FIGURE LEGENDS**

515

516 **FIG 1** Geographical distribution and isolation sources of publicly available *A. baumannii*

517 strains carrying plasmids. A) Geographical distribution of plasmid-containing strains, colour-

518 coded by the number of genomes accessible in GenBank as of August 2022. B) Isolation

519 sources of plasmid-carrying strains, depicted with a scale bar provided above.

520

521 **FIG 2** Phylogenetic relationship and distribution of antimicrobial resistance determinants in

522 R1-type plasmids across major globally distributed sequence types and global clones. Plots

523 show the plasmids linked with a particular plasmid type, with each data point corresponding

524 to a unique plasmid, grouped by chromosomal sequence type/clone, and coloured by

525 geographical region as shown in the Figure key. Empty circles (marked no AMR) indicate the

526 absence of antimicrobial resistance gene.

527

528 **FIG 3** Schematic comparison of Rep_3 family (R3-type; Pfam01051) plasmid structures.

529 Horizontal arrows show the length and orientation of genes with *rep* genes coloured black,

530 resistance genes red, toxin/anti-toxins yellow and mobilisation genes blue. Green boxes

531 indicate insertion sequences with their transposase shown inside the box. Small thick vertical

532 bar marked with “i” indicate iterons. Dotted lines draw the show the boundaries of *pdif*

533 modules. Other vertical bards marked with “C/D or D/C” indicate the location of *pdif* sites.

534 Regions with significant DNA identities are shown using shades of grey with % identities

535 also shown using red numbers.

536

537 **FIG 4** Phylogenetic relationship and distribution of antimicrobial resistance determinants in
538 R3-type plasmids across major globally distributed sequence types and global clones. The
539 overall phylogenetic tree is depicted in panel A), and clades 1 and 2 shown in greater resolution
540 in panels B) and C), respectively. Nodes that are coloured red correspond to plasmid types
541 where the presence of antimicrobial resistance genes is detected in at least one plasmid. Plots
542 in panels B and C show the number of plasmids linked with a particular plasmid type; each
543 data point corresponds to a unique plasmid, grouped by chromosomal sequence type/clone, and
544 is coloured by geographical region as shown in the Figure key. Empty circles indicate plasmids
545 with no AMR, triangles indicate plasmids with carbapenemases and filled circles represent
546 plasmids with AMR (no carbapenemase). Data for three variants corresponding to R3-T3, R3-
547 T4 and R3-T1 types are separately shown at due to spacing.

548

549

550 **FIG 5** Phylogenetic relationship and distribution of antimicrobial resistance determinants in
551 RP-type plasmids across major globally distributed sequence types and global clones. Plots
552 show the number of plasmids linked with a particular plasmid type; each data point
553 corresponds to a unique plasmid, grouped by chromosomal sequence type/clone, and is
554 coloured by geographical region as shown in the Figure key. Empty circles indicate plasmids
555 with no AMR, triangles indicate plasmids with carbapenemases and filled circles represent
556 plasmids with AMR (no carbapenemase).

557

558 **FIG 6** Linearised map of pD36-1 (cryptic) compared with pRAY* (pD36-2). Central horizontal
559 lines indicate the plasmid backbones. Arrows represent the extent and orientation of genes, and
560 the gene cassette is boxed. The grey shadings indicate regions with significant identity with the

561 % identities indicated in red. Scale bar is shown. Drawn to scale from GenBank accession
562 numbers CP012954 (pRAY*), and CP012953 (pD36-1).

563
564 **Supplementary FIG 1** Genetic structure of pACICU2 representing plasmids that encode RP-
565 T1 replication initiation protein. Arrows indicate the extent and orientation of genes and open
566 reading frames with red showing resistance genes, black *rep*, and flax transfer genes. Boxes
567 coloured green indicate ISAbal25 copies.

568
569 **Supplementary FIG 2** Circular map of pA297-3 drawn to scale from GenBank accession
570 number KU744946. Arrows represent the orientation and extent of genes and open reading
571 frames. Open reading frames with no predicted function are white and antimicrobial resistance
572 genes are coloured red. Insertion sequences (IS) are shown with filled boxes coloured different
573 shades of green. Arrows coloured flax represent the *tra* genes, which are involved in plasmid
574 transfer. Gray arrows represent genes/orfs involved in DNA metabolism.
