A Novel Extreme Learning Machine for Hypoglycemia Detection

Phyo Phyo San, Sai Ho Ling Senior Member, IEEE, Ni Ni Soe, and Hung T. Nguyen Senior Member, IEEE

Abstract—Hypoglycemia is a common side-effect of insulin therapy for patients with type 1 diabetes mellitus (T1DM) and is the major limiting factor to maintain tight glycemic control. The deficiency in glucose counter-regulation may even lead to severe hypoglycaemia. It is always threatening to the well-being of patients with T1DM since more severe hypoglycaemia leads to seizures or loss of consciousness and the possible development of permanent brain dysfunction under certain circumstances. Thus, an accurate early detection on hypoglycaemia is an important research topic. With the use of new emerging technology, an extreme learning machine (ELM) based hypoglycaemia detection system is developed to recognize the presence of hypoglycaemic episodes. From a clinical study of 16 children with T1DM, natural occurrence of nocturnal hypoglycaemic episodes are associated with increased heart rates ($p < 0.06$) and increased corrected QT intervals ($p < 0.001$). The overall data were organized into a training set with 8 patients (320 data points) and a testing set with 8 patients (269 data points). By using the ELM trained feed-forward neural network (ELM-FFNN), the testing sensitivity (true positive) and specificity (true negative) for detection of hypoglycaemia is 78 and 60% respectably.

I. INTRODUCTION

Hypoglycaemia, or low blood glucose levels, is one of the most common side effects among individuals with Type 1 diabetes. It is also well known as a barrier for achieving and maintaining tight glycemic control. Individuals who experience frequent episodes of hypoglycaemia and those who have been on insulin therapy for a long period of time may develop impaired awareness of hypoglycaemia. Impaired hypoglycaemic awareness occurs in approximately 25% of individuals with type 1 diabetes. Severe hypoglycaemia may lead to physical and psychosocial morbidity such as brain damage, loss of consciousness, depression and low self-esteem [1]. It is also well known as death-in-bed syndrome [10].

To prevent or minimize hypoglycaemic morbidity and mortalities, it is vital to return the blood glucose level to normal soon after a hypoglycaemic event occurs. The patients’ conditions are obviously need to know; when the event of hypoglycaemia is initiated, and/or how the early warning is detected [3]. In other words, the need for hypoglycaemia detection device is essential in order for giving alarm alert to Type 1 diabetes patients or carer when low blood glucose level is detected.

To analyze the blood glucose level (BGL) as well as the presence of hypoglycaemia, many monitoring systems have been developed to be invasive or minimally invasive with the use of a needle-type probe [4]. However, this kind of measurement can only provide an isolated glucose level which does not reflect variations occurring throughout the day and night. For serve hypoglycaemia, monitoring BGL continuously becomes almost impossible task, especially during the stage of nocturnal hypoglycaemia.

Other minimally invasive devices [6] or non-invasive devices [7] have been tested and introduced with the aid of current technologies such as reverse iontophoresis, suction effusion fluid and near-infrared spectroscopy. But they suffer from limitations in terms of measurement inaccuracy, high susceptibility to artefact noise, considerable time delays for obtaining results and long-term reproducibility. The complications which are inherent with these techniques limit their use as practical non-invasive hypoglycaemic monitors.

An alternative idea and solutions are still needed for non-invasive continuous monitoring of BGL as well as for prediction of hypoglycaemia. To get a hold of this requirement, hypoglycaemia detection systems have been investigated by the use of physiological parameters that are stimulated by falling blood glucose levels. For instance, Teledyne Sleep Sentry [8], multiparameter measurement system, Mini Med Medtronic CGMS and Abbott Freestyle Navigator CGMS [11].

Based on the strong relationship between physiological parameters and hypoglycaemia, a non-invasive hypoglycaemia monitor was tested and introduced by the use of the physiological parameters (heart rate (HR), corrected QT interval (QTc) and skin impedance) [12] [13]. By employing Bayesian neural network algorithm, the obtained sensitivity was found to be satisfactory, but the specificity need to be improved. More advanced neural network algorithms are still needed for obtaining better testing sensitivity and specificity. In addition, fuzzy estimator [14], fuzzy neural network estimator [15] were proposed for hypoglycaemia detection systems. In these systems, the status of hypoglycaemia was predicted through the changes in physiological parameters of the ECG signal. However, the membership functions which express the linguistic terms for fuzzy inference rules have to be defined. In practise, there is no formal approach for defining these rules and the optimization of these membership functions in terms of generalizing the data is also very important. Usually, tuning parameters of membership function is a time consuming task.
In [16] [17], an evolved fuzzy reasoning model was developed to recognize the presence of hypoglycemic episodes. The physiological parameters such as heart rate and corrected QT interval of the electrocardiogram (ECG) signal were continuously measured for early detection of hypoglycemic episodes in Type 1 diabetes mellitus (T1DM) patients. In evolved FRM, the fuzzy rules and fuzzy membership functions were optimized by an evolutionary algorithm called hybrid particle swarm optimization with wavelet mutation (HPSOWM). The results showed that the proposed algorithm performed well in terms of the clinical sensitivity and specificity. However, in evolved FRM, more parameters were needed to be optimized. Hence, it is desirable to have an automatic adaption procedure with less design parameters.

Further experiment were conducted by the use of neural network based rule discovery system [18]. The development was based on 420 data sets which were collected from 16 T1DM patients by using the genetic algorithm. Though the obtained sensitivity and specificity are reasonable, the neural network used in the developed detection system might not be able to improve further because its slow learning speed and poor computational scalability.

To overcome some challenges faced by the mentioned state-of-the-art computational intelligence techniques, an emerging new technique named as extreme learning machine (ELM) [20] has been brought to the considerable attention. Generally, ELM is used to train for single-hidden layer feed-forward neural network (FFNN). Different from common understanding of learning algorithm for FFNN, its hidden node parameters are randomly generated and no need to be tuned. Besides, it is able to achieve the smallest training error as well as the smallest norm of output weights. Due to its significant features including faster learning speed and better generalization, in this paper, an ELM based hypoglycemia detection system is developed.

The organization of this chapter is as follows: in Section II, a single layer feedforward neural network (FFNN) and an emerging new training algorithm, extreme learning machine (ELM) is introduced. To show the effectiveness of our proposed methods, the results of early detection of nocturnal hypoglycemia are discussed in Section III and a conclusion is drawn in Section IV.

II. METHODS

To recognize the status of hypoglycemic episodes in T1DM, an ELM based hypoglycemia detection system in Fig. 2 is developed by the use of physiological parameters of ECG signal Fig. 1.

For patient with Type1 and Type2 diabetes, the possibility of hypoglycemia is mainly effected by prolongation of QT intervals (starting from the point of Q wave to at the end of T wave) and its correlation to heart rate is carried out by Bazett’s formula $QT = QTc/HR$ [19]. Not only QT interval prolongation has a significant impact on hypoglycemia, but an increase in heart rate (HR) also may influence the status of hypoglycemia. With these change of physiological parameters, in this paper, an ELM based hypoglycemia detection system is developed for early detection of hypoglycemic episodes. The proposed ELM based model with four inputs such as heart rate (HR), corrected QT interval ($QTc$), change of heart rate and corrected QT interval, ($ΔHR$) and ($ΔQTc$) and one output system (hypoglycemia status ($h$)) is developed as shown in Fig. 2.

A. Extreme Learning Machine (ELM)

In this section, extreme learning machine (ELM) for the training of single hidden layer feedforward neural network (FFNN) in Fig. 3 is presented. Compared with the conventional neural network learning algorithms, it can achieve faster training performance and overcome the problem of over-fitting. The algorithm is based on the empirical risk minimization theory. Its learning process needs only for a single iteration and is able to avoid multiple iterations and local minimization. Because of better generalization ability, robustness, and controllability and faster learning process, it has been used in many real world applications [21]. For N arbitrary distinct samples $(x_i,t_i) \in \mathbb{R}^d \times \mathbb{R}^m$, the mathematically model of FFNN with $L$ hidden nodes can be written as:

$$y_j = \sum_{i=1}^L \beta_i g_i(x_j) = \sum_{i=1}^L \beta_i G(a_i,b_i,x_j), \quad j = 1, \ldots, N$$

(1)

The FFNN can approximate these $N$ samples with zero error means that $\sum_{i=1}^L \|y_j - t_j\| = 0$, i.e., there exist $(a_i,b_i)$ and $\beta_i$ such that $\sum_{i=1}^L \beta_i G(a_i,b_i,x_j) = t_j$, whereas $j = 1, \ldots, N$. It can be expressed as:

$$H\beta = T$$

(2)

where

$$H = \begin{bmatrix} h(x_1) \\ \vdots \\ h(x_N) \end{bmatrix} = \begin{bmatrix} G(a_1,b_1,x_1) & \cdots & G(a_1,b_1,x_N) \\ \vdots & \cdots & \vdots \\ G(a_1,b_1,x_1) & \cdots & G(a_1,b_1,x_N) \end{bmatrix}$$

$$T = \begin{bmatrix} t_1 \\ \vdots \\ t_N \end{bmatrix}$$

(3)
According to conventional neural network theories, hidden layer parameters, i.e., weight and biases \((a_i, b_i)\) and the output weights \(\beta_i\) need to be tuned properly and searching for optimal parameters. Much efforts have been tried for obtaining better way of finding and adjusting hidden layer parameters \((a_i, b_i)\). In [22], incremental learning method which mainly focus and adjust on the newly added hidden nodes rather than adjusting all the hidden nodes parameters. In contrast, all the parameters of FFNN such as weight \((a_i)\) and biases \((b_i)\) and the output weight parameters \((\beta_k)\) need not be tuned and can be independent of training samples.

Similar to the conventional neural network, the numbers of hidden nodes are chosen by trial and error method until the optimal solution is obtained. However, there is a trade-off between too less number and too many numbers of hidden nodes because less number of node is insufficient to give the optimal solution and more numbers may unnecessarily increase the number of parameters to be tuned by ELM.

In essence, the ELM need to be iteratively tuned and both the training error and the norm of weight can be minimized as long as the hidden layer feature mapping need to satisfy approximation condition [23]. In ELM, the hidden nodes can be randomly generated and the output weights vector \(\beta_i\) is the only unknown parameters which can be resolved by ordinary least-square directly. Unlike the traditional computational intelligence techniques, ELM also provide better generalization performance at a much faster convergence rate without over-fitting problem.

III. RESULT AND DISCUSSION

In this group of study, all 16 patients (children with ages 14.6 ± 1.5 years) were Type 1 diabetes patients and they underwent for overnight electrocardiogram (ECG) and glucose monitoring at the Princess Margaret Hospital for Children in Perth, Australia. For each patient, all the data were collected between 360 minutes to 480 minutes and approximately 35-40 data points were collected for a sampling period of between 5 and 10 minutes.

The relationships between overnight measurements of QT interval corrected for heart rate (QTc) and falling BGL were discovered by the use of statistical correlation analysis. The overall data set of 16 children with Type 1 diabetes [12] were considered in this study due to their significant increment in HR and QTc in response to episodes of hypoglycemia (1.033 ± 0.242 vs. 1.082 ± 0.084 < 0.001). To perform the classification test, the overall data set consisted of a training set with 8 patients (320 data points) and a testing set with 8 patients (269 data points), randomly selected.

For comparison and analysis purposes, five methods are applied to the hypoglycemia detection problem as following:

1. Proposed feed-forward neural network trained with ELM with 15 hidden nodes (FFNN-ELM);
2. Feed-forward neural network trained with particle swarm optimization (FFNN-PSO[17]);
3. Second order multiple regress fuzzy inference system...
(MR-FIS) [16];
4. Fuzzy inference system with 5 membership functions for each input (FIS) [17];
5. Linear multiple regression (LMR) [16].

All of the methods are applied into the hypoglycemia detection system where the four inputs of the system are heart rate (HR), QT interval (QTc), ∆HR and ∆QTc and one output to represent the onset of hypoglycemia. The testing results in term of sensitivity and specificity are tabulated in Table I. Moreover, the training time for all methods are also shown in the same table to illustrate how fast of the proposed method compared with other methods. In Table I, we can seen that the testing sensitivity and specificity of proposed ELM based FFNN achieve 78 and 60% which is better than 75.00% testing sensitivity and 50.23% specificity given by multiple regression with fuzzy inference system (MR-FIS) [16]. Also, compared with FFNN-PSO which is trained by PSO, the testing performance of the FFNN trained by ELM is outperformed. Besides, the proposed FFNN-ELM gives a faster training time which is about 3 mins, while the other methods (FFNN-PSO, MR-FIS, and FIS) take around 30 to 275 mins. LMR gives a very fast training time, however, the testing performance is unacceptable. In Summary, the FFNN-ELM gives satisfactory results with faster training time.

**IV. CONCLUSIONS**

For detection of the hypoglycemic episodes for diabetes patients an ELM based diagnosis system has been developed. The above results indicate that hypoglycemic episodes in T1DM children can be detected non-invasively and effectively by the use of real-time physiological parameters of ECG signal. The performance of proposed detection system is evaluated with other comparison methods and the improvement in sensitivity can be satisfactorily found with faster training time.
