21 **Abstract**

22 Anaerobic digestion is a promising technology for energy recovery from secondary sludge, yet the  
23 presence of humic substances in wastewater limits anaerobic digestion. In particular, humic substances  
24 make secondary sludge denser and more compact, reducing the availability of organic matter for  
25 biodegradation. Here we review the impact of humic substances on the anaerobic process, with emphasis  
26 on humic substances properties, effect on sludge structure and composition, effect on hydrolysis,  
27 acidolysis and methanogenesis, evolution of humic substances, and strategies to counteract negative  
28 impact. Strategies include removing humic substances, pretreatment of secondary sludge prior anaerobic  
29 digestion, and addition of metal salts, enzymes and organisms. We observed that humic substances with  
30 a high E4/E6 ratio, representing the absorbance determined at 465 nm and 665 nm, a low carbon/nitrogen  
31 ratio, and a low aromaticity are easier to digest anaerobically. The liquid-solid phases distribution of  
32 humic substances influences anaerobic digestion efficiency, and the repolymerisation of humic  
33 substances during anaerobic digestion reduces sludge degradability.

34 **Keywords** Humic substances · Structure and composition of sludge · Dynamic evolution · Mitigate  
35 inhibition strategies · Metal salts

1 57 2019a). Diverse methods have been adopted to enhance methane accumulation in  
2  
3 58 anaerobic digestion, such as optimization of operational conditions (Wu et al. 2019),  
4  
5  
6 59 the addition of additives (Feng et al. 2014), and pre-treatment before anaerobic  
7  
8  
9 60 digestion (Li et al. 2016). While these techniques facilitated the destruction and the  
10  
11  
12 61 subsequent energy recovery from secondary sludge, they also released more humic  
13  
14  
15 62 substances from the solid to the liquid phase, becoming an inhibitor to energy recovery  
16  
17  
18 63 from secondary sludge in anaerobic digestion.

19  
20  
21  
22 64 Humic substances are typical compounds in secondary sludge, accounting for 20–30%  
23  
24  
25 65 of volatile solids (Xu et al. 2020). They usually possess the characteristics of a large  
26  
27  
28 66 molecular size, aromatic structure, and oxygen-containing functional groups, which  
29  
30  
31 67 complicate decomposition and further utilisation by anaerobes (Li et al. 2017b). Humic  
32  
33  
34 68 substances in secondary sludge are sourced from dead microorganisms, animal residues,  
35  
36  
37 69 and plant degradation and polymerisation (Liang et al. 2021; Xu et al. 2020), while  
38  
39  
40  
41 70 some have been found to generate *in situ* during anaerobic digestion processes due to  
42  
43  
44 71 the transformation of protein-like substances (Dai et al. 2013). The inhibition effects of  
45  
46  
47 72 humic substances on anaerobic digestion have been observed to reduce methane  
48  
49  
50 73 production (Li et al. 2021; Liu et al. 2019a), likely due to the inhibition by humic  
51  
52  
53 74 substances of functional enzyme activities associated with hydrolysis and acidification  
54  
55  
56 75 (Huang et al. 2021), as well as competition between humic substances and methanogens  
57  
58  
59 76 for electrons (Li et al. 2019b). However, inconsistent observations have also been  
60  
61  
62 77 reported in which humic substances acted as promoters that facilitated methane yield  
63  
64  
65

1 78 (Huang et al. 2021; Zhou et al. 2014). The effect of humic substances on anaerobic  
2  
3 79 digestion processes and the associated mechanisms thus remains poorly summarised.  
4  
5  
6 80 Furthermore, various technologies have been proposed to alleviate the inhibition of  
7  
8  
9 81 anaerobic digestion processes by humic substances, such as the removal of humic  
10  
11  
12 82 substances from wastewater, the pretreatment of secondary sludge before anaerobic  
13  
14  
15 83 digestion, the addition of metal salts, and the addition of enzymes or the introduction  
16  
17  
18 84 of endogenous or exogenous organisms (Azman et al. 2015; Hu et al. 2022; Li et al.  
19  
20  
21 85 2014; Li et al. 2021; Millati et al. 2020). However, the performance of these methods  
22  
23  
24 86 has greatly varied (Fernandes et al. 2015; Li et al. 2021). To date, a comprehensive  
25  
26  
27 87 summary of the mechanisms and mitigation strategies related to humic substances in  
28  
29  
30 88 anaerobic digestion processes remains lacking, which hinders the development of  
31  
32  
33 89 energy recovery from secondary sludge using these processes.

34  
35  
36 90 This review aims to introduce novel insights into the impact of humic substances on  
37  
38  
39 91 anaerobic digestion processes, addressing key aspects that have not been  
40  
41  
42 92 comprehensively summarized before. Specifically, this review focuses on I) unveiling  
43  
44  
45 93 the characteristics of humic substances and their impact on the structure and  
46  
47  
48 94 composition of secondary sludge; II) investigating the intricate influence of humic  
49  
50  
51 95 substances on crucial steps of anaerobic digestion processes, i.e., hydrolysis,  
52  
53  
54 96 acidification, and methanogenesis, shedding new light on their complex interactions;  
55  
56  
57 97 III) exploring the dynamic evolution of humic substances in anaerobic digestion  
58  
59  
60 98 processes, providing novel insights into their transformation and behavior; and IV)

1 99 examining the effects and mechanisms of methods that mitigate inhibition of anaerobic  
2  
3 100 digestion by humic substances, presenting promising approaches for improving energy  
4  
5  
6 101 recovery efficiency. This review deepens our understanding of the effects of humic  
7  
8  
9 102 substances on anaerobic digestion processes and provides challenges and research  
10  
11  
12 103 recommendations for future research development.

## 16 104 **2. Influence of humic substances on secondary sludge structure**

### 17 18 19 20 105 2.1 Characteristics of humic substances

21  
22  
23  
24 106 Humic substances are the second-most abundant organic substance in secondary sludge,  
25  
26  
27 107 accounting for 20–30% of the volatile solids (Wang et al. 2023; Xu et al. 2020). They  
28  
29  
30 108 originate from wastewater and are enriched in secondary sludge due to biosorption  
31  
32  
33 109 (Kulandaivelu et al. 2020; Ryu et al. 2021). Nonetheless, the definitive structure of  
34  
35  
36 110 humic substances remains undefined, owing to their diverse chemical composition  
37  
38  
39 111 (Baveye and Wander 2019). Noteworthy, the average elemental composition of humic  
40  
41  
42 112 substances is relatively consistent, mainly composed of carbon, oxygen, nitrogen,  
43  
44  
45 113 hydrogen, and sulfur (Nardi et al. 2021). Previous studies have reported that humic  
46  
47  
48 114 substances originated from numerous materials such as leonhardite, soil, and compost  
49  
50  
51 115 manure, which typically exhibit similar levels of carbon content, but differ in terms of  
52  
53  
54 116 oxygen, hydrogen, and nitrogen content. In contrast, humic substances obtained from  
55  
56  
57 117 secondary sludge are characterized by a high concentration of nitrogen and hydrogen  
58  
59  
60 118 and a low concentration of oxygen in their composition (Yang and Li 2016). Humic  
61  
62  
63  
64  
65

1 119 substances also contain diverse functional groups, including carboxyl, alcoholic  
2  
3 120 hydroxyl, quinone, ketone, and phenolic groups (Lipczynska-Kochany 2018; Wang et  
4  
5  
6 121 al. 2022c). This structure allows humic substances to combine with diverse organic  
7  
8  
9 122 matter, such as organic acids, fatty acids, lipids, amino acids, and others (Nardi et al.  
10  
11 123 2021).

12  
13  
14  
15  
16 124 Based on water solubility, humic substances can be further divided into three categories:  
17  
18 125 humic acid (soluble at  $\text{pH} > 2$ ), fulvic acid (soluble at all pH values), and humin  
19  
20 126 (insoluble at all pH values) (Ghaneian et al. 2014; Liu et al. 2019a). These fractions can  
21  
22 127 vary remarkably in their chemical composition, molecular size, and properties, such as  
23  
24 128 hydrophobicity, and aromaticity (Rigobello et al. 2017). Moreover, the structure of  
25  
26 129 humic substances is dynamic and can be influenced by various environmental factors  
27  
28 130 such as pH, and ionic strength, which dominates the size and shape of the specific  
29  
30 131 fraction of humic substances (Klučáková 2018).

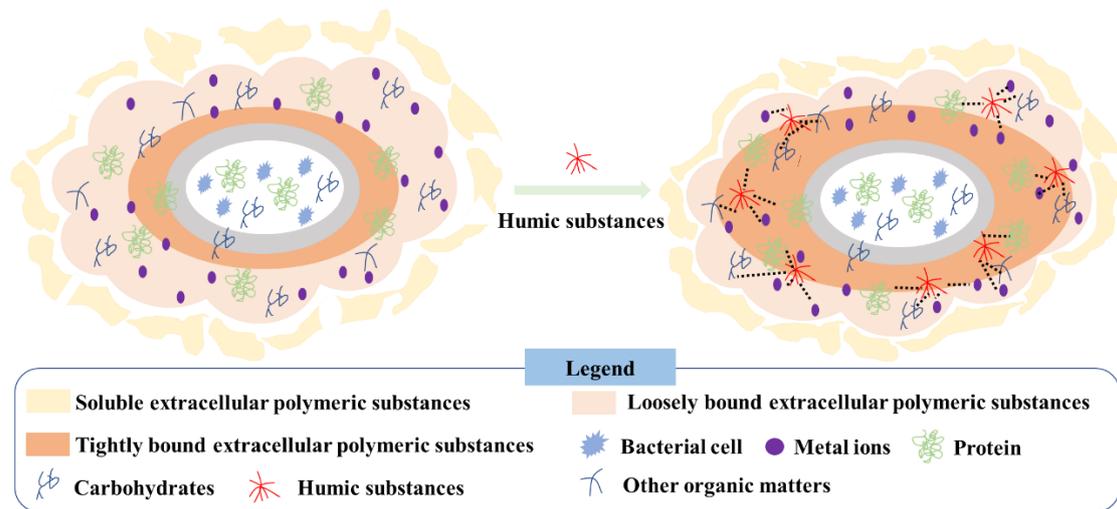

## 31 132 2.2 Effect of humic substances on secondary sludge structure and composition

32  
33  
34  
35  
36  
37  
38  
39  
40  
41  
42  
43

44 133 Typically, sludge flocs (Fig. 1) mainly contains three layers, namely soluble, lightly  
45  
46 134 bound, tightly bound extracellular polymeric substances (Liu et al. 2020), and consisted  
47  
48 135 of humic substances, protein, carbohydrate, bacteria cell, metal ions, and other organic  
49  
50 136 matters, and so on (Kulandaivelu et al. 2020; Wang et al. 2023). Humic substances  
51  
52 137 develop strong links (dotted line in Fig. 1) with inorganic, such as metal ions and  
53  
54 138 organic matter, such as proteins and polysaccharides, which lowers the solubility of the  
55  
56  
57  
58  
59  
60  
61  
62  
63  
64  
65

1 139 latter in secondary sludge. Furthermore, the functional groups of humic substances react  
2  
3 140 with biodegradable organic matter through absorption, sedimentation, and aggregation  
4  
5  
6 141 (He et al. 2016; Siddiqui et al. 2020; Xu et al. 2020; Zhou et al. 2023), and with  
7  
8  
9 142 inorganic matter through the bridge, electrostatic, and steric interactions (Calabi-Floody  
10  
11  
12 143 et al. 2011; Zhang et al. 2021b), which result in a more compact, denser, and stable  
13  
14  
15 144 secondary sludge structure (Fig. 1). For example, the addition of humic substances  
16  
17 145 enhanced the fractal dimension of sludge by 8.7% and decreased the total surface energy,  
18  
19  
20 146 soluble total organic carbon, and transverse relaxation times by 5.8%, 36.1%, and  
21  
22  
23 147 24.4%, respectively, indicating that humic substances can combine with organic matter  
24  
25  
26 148 in secondary sludge and improve the sludge floc structural stability (Xu et al. 2020).  
27  
28 149 Additionally, the enhancement of extracellular polymeric substances' spatial  
29  
30  
31 150 configuration, along with the decrease in its random-coil degree due to humic  
32  
33  
34 151 substances, reduces the active sites in extracellular polymeric substances in  
35  
36  
37 152 combination with extracellular enzymes (Xu et al. 2020), which inhibits the hydrolysis  
38  
39  
40 153 and acidification potential of secondary sludge in anaerobic digestion processes.  
41  
42  
43  
44 154 Apart from influencing the structures of organic substances in secondary sludge, humic  
45  
46  
47 155 substances also affect their organic substance composition (Yang et al. 2019) due to  
48  
49  
50 156 their nature as recalcitrant substances and important components of the organic matter  
51  
52  
53 157 (Wang et al. 2019b). Studies have confirmed that pretreatment efficiently promotes  
54  
55  
56 158 sludge anaerobic digestion efficiency, as shown by significant changes in recalcitrant  
57  
58  
59 159 substance content, such as humic substances during pretreatment conditions (Liu et al.

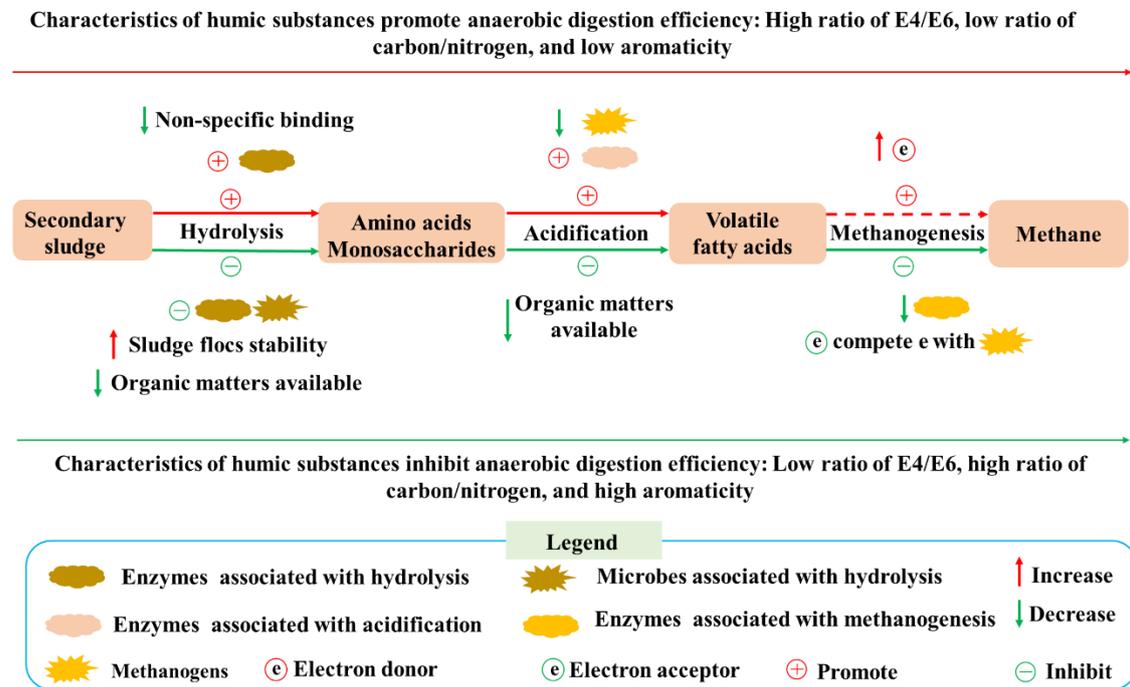

160 2020; Wang et al. 2022b). However, in most cases, the hydrolysis degree of secondary  
 161 sludge is represented by protein and polysaccharide variations, while the recalcitrant  
 162 organic substance variation is not included (Lu et al. 2020). A suitable index is thus  
 163 needed to describe the variation of recalcitrant organic substances. Three-dimensional  
 164 fluorescence spectroscopy can provide a pathway to analyze the amount of recalcitrant  
 165 organic substances and a reference for future studies (Geng and Zhou 2022). This  
 166 technology has been successfully used to quantify variations of humic substances  
 167 content, such as changes from 33.26% to 23.05%, 36.2% to 15.9%, and 29.4% to 10.5%  
 168 after pretreatment with sodium percarbonate (Wang et al. 2022b), heat-CaO<sub>2</sub> (Liu et al.  
 169 2019b), and sulfite (Liu et al. 2020), respectively. Overall, the impact of humic  
 170 substances on the structure and composition of secondary sludge might affect the  
 171 efficiency of anaerobic digestion, as discussed in the following.

172  
 173 **Figure 1.** Proposed humic substances' interactions with organic and inorganic  
 174 substances in sludge. The presence of humic substances can make secondary sludge  
 175 denser and more compact, reducing the availability of organic matter.

176 **3. Humic substances on the influence of each stage in anaerobic digestion**

177 Anaerobic digestion of secondary sludge typically involves three interlinked stages:  
 178 hydrolysis, acidification, and methanogenesis (Guo et al. 2022). In the hydrolysis stage,  
 179 polysaccharides and proteins are transformed into monosaccharides and amino acids.  
 180 Hydrolysis products are further transformed into short-chain fatty acids in the  
 181 acidification stage. These acidification products are ultimately transformed into  
 182 methane as the end-product of anaerobic digestion. The impact of humic substances on  
 183 anaerobic digestion efficiency in each stage and the associated mechanisms are  
 184 discussed in the following sections (and summarised in Table 1 and Fig. 2).

186 **Figure 2.** Influence of humic substances on each stage of anaerobic digestion. Note:  
 187 E4/E6 refers to the ratio of absorbance determined at 465 nm and 665 nm (E6) of humic

1 188 substances.

<b>Negative:</b> increases sludge floc structural stability, reducing organic content availability	<b>Negative:</b> less amount of low molecular quality organic substances available	<b>Negative:</b> changes the accessibility of hydrolysis products, leading to poor anaerobic bioconversion	Commercial humic substances	Xu et al. (2020)

---

190 Note: E4/E6 refers to the ratio of absorbance determined at 465 nm and 665 nm of humic substances. SHHA means commercial humic substances  
191 from Shanghai Reagent Company.

1  
2 192 3.1 Hydrolysis stage  
3  
4

5 193 Conflicting observations have been reported regarding the influence of humic  
6  
7  
8 194 substances on the hydrolysis stage of anaerobic digestion (Table 1). Tang et al. (2020a)  
9  
10  
11 195 demonstrated that the efficiency of enzymatic hydrolysis increased from 64.9% to 81.8%  
12  
13  
14 196 in the presence of humic substances (obtained from waste wheat straw), which reduced  
15  
16  
17 197 the non-specific binding of hydrolase. Liu et al. (2015) revealed that the strong  
18  
19  
20 198 hydrophobicity of commercial humic substances benefitted the formation of protective  
21  
22  
23 199 micelles, which enhanced hydrolytic enzyme activity, including protease and  $\alpha$ -  
24  
25 200 glucosidase, thus accelerating hydrolysis. Similar observations were reported by Wang  
26  
27  
28 201 et al. (2022a) using humic substances derived from sludge and by Hartung (1992) using  
29  
30  
31 202 humic substances obtained from peat, which respectively increased the electron transfer  
32  
33  
34 203 capacity or the activity of microorganisms responsible for hydrolytic enzyme secretion  
35  
36 204 and hydrolysis promotion.

37  
38  
39  
40  
41 205 In contrast, Huang et al. (2021) found that proteinase activity decreased by 20% under  
42  
43  
44 206 a 7.5 mg humic substances/g volatile solids stress condition, which was attributed to  
45  
46  
47 207 hydrolytic protease inhibition due to the interaction between humic substances and  
48  
49  
50 208 functional enzymes or substrates and the accumulation of humic substances (from  
51  
52  
53 209 sludge) outside anaerobe cells. This research also found that a low E4/E6 ratio (refers  
54  
55  
56 210 to the ratio of the absorbance determined at 465 nm and 665 nm) and high  
57  
58 211 carbon/nitrogen ratio under humic substances stress conditions make humic substances  
59  
60  
61  
62  
63  
64  
65

1 212 more difficult to decompose in the hydrolysis stage of anaerobic digestion and increase  
2  
3 213 the possibility of the combination between enzymes and humic substances (Huang et  
4  
5  
6 214 al. 2021). The presence of humic substances resulted in up to 38.2% inhibition of  
7  
8  
9 215 hydrolysis due to their superior mobility and easy contact with enzymes, i.e., proteinase  
10  
11  
12 216 and  $\alpha$ -amylase, and such inhibition effects were dependent on both the concentration  
13  
14  
15 217 and structure of humic substances (Li et al. 2019b). Azman et al. (2017) observed up to  
16  
17  
18 218 40% inhibition of hydrolysis efficiency by humic substances, which was attributed to  
19  
20  
21 219 the reduced hydrolytic bacterial activity, such as *Clostridiales*, *Bacteroidales*, and  
22  
23 220 *Anaerolineales*. Another study additionally revealed that humic substances enhanced  
24  
25  
26 221 sludge floc structural stability, which reduced the organic content bioavailable to  
27  
28  
29 222 anaerobes in the liquid phase, thus inhibiting hydrolysis efficiency (Xu et al. 2020).  
30  
31  
32  
33 223 Inconsistent observations of the impact of humic substances on hydrolysis are likely  
34  
35  
36 224 caused by the sources, structures, molecular weights, functional groups, and  
37  
38  
39 225 concentrations of humic substances, as well as the microbial community in the  
40  
41  
42 226 secondary sludge. Specifically, the presence of humic substances has promoted  
43  
44  
45 227 hydrolysis as in Tang et al. (2020a), Liu et al. (2015), and Huang et al. (2021), but the  
46  
47  
48 228 magnitudes of these changes have varied greatly. This may be caused by the different  
49  
50  
51 229 sources of humic substances (waste wheat straw versus commercial humic substances  
52  
53 230 versus peat). Nonetheless, although both Wang et al. (2022a) and Huang et al. (2021)  
54  
55  
56 231 utilized humic substances from sludge, hydrolysis was promoted in the former but  
57  
58 232 inhibited in the latter study. This discrepancy might be due to differences in the humic  
59  
60  
61  
62  
63  
64  
65

1 233 substances' structure and functional groups. Those in Wang et al. (2022a) possessed  
2  
3 234 higher nitrogen-content and oxygen-containing groups than those in Huang et al. (2021),  
4  
5  
6 235 which potentially increased the electron transfer capacity. This higher capacity  
7  
8  
9 236 subsequently may have made the interactions between negatively charged humic  
10  
11  
12 237 substances and enzymes stronger than those between hydrophobic interactions and  
13  
14  
15 238 enzymes, resulting in the release of hydrolytic enzymes and facilitating their activity  
16  
17  
18 239 (Li et al. 2019a; Liu et al. 2015). Moreover, greater inhibition of hydrolysis efficiency  
19  
20  
21 240 by humic substances was observed in (Azman et al. 2017), although the same  
22  
23  
24 241 commercial humic substances were used. Such differences might be related to  
25  
26  
27 242 variations in the humic substances concentrations and corresponding differences in the  
28  
29  
30 243 microbial community adaptation capacity.

### 31 32 33 244 3.2 Acidification stage 34 35

36  
37 245 Most studies have revealed the positive effects of humic substances on the acidification  
38  
39  
40 246 process during anaerobic digestion (Li et al. 2019b; Liu et al. 2015; Wang et al. 2022a).  
41  
42  
43 247 For example, the short-chain fatty acid yield increased from 1379 mg chemical oxygen  
44  
45  
46 248 demand (used as an indicator that measures the amount of oxygen consumed by  
47  
48  
49 249 inorganic and organic compounds)/L to 2741 mg chemical oxygen demand/L when the  
50  
51  
52 250 dosage of SHHA (commercial humic substances from Shanghai Reagent Company)  
53  
54  
55 251 increased from 420 mg-SHHA/g volatile solids to 1120 mg-SHHA/g volatile solids,  
56  
57  
58 252 possibly because the presence of quinone structures in the humic substances accelerated  
59  
60  
61 253 the bioreactions of pyruvate to acetyl-CoA and glyceraldehyde-3p to D-glycerate 1,3-

1 254 diphosphate (Liu et al. 2015). Li et al. (2019b) also observed a 101.5% increase in  
2  
3 255 acidogenic efficiency at 150 mg humic substances/g volatile solids. Additionally, a  
4  
5  
6 256 recent study revealed that humic substances contributed to electron transfer chains and  
7  
8  
9 257 acted as catalysts, promoting the activities of enzymes responsible for the acidification  
10  
11  
12 258 stage, such as acetate kinase, phosphotransacetylase, and butyric kinase (Wang et al.  
13  
14  
15 259 2022a). Notably, the electron transfer chain contains two parts (electron acceptor  
16  
17 260 capacity and electron donor capacity); the former was determined by nitrogen content,  
18  
19  
20 261 humification index, oxygen-containing groups, and aromatic groups (Tan et al. 2017),  
21  
22  
23 262 while the latter was only determined by nitrogen content and oxygen-containing groups  
24  
25  
26 263 (Wang et al. 2022a).

27  
28  
29  
30 264 In contrast, some studies showed an inhibitory effect of humic substances on the  
31  
32  
33 265 acidification stage of anaerobic digestion (Huang et al. 2021; Xu et al. 2020). The  
34  
35  
36 266 concentration of short-chain fatty acids decreased from 9800 to 4800 mg/L, and the  
37  
38  
39 267 acidification rate was inhibited by 50% when the humic substances concentration  
40  
41  
42 268 increased from 1.0 to 2.5 mg humic substances/g volatile solids (Huang et al. 2021).  
43  
44  
45 269 This phenomenon might be attributed to the low E4/E6 and high carbon/nitrogen ratios  
46  
47  
48 270 of humic substances, making them more difficult to decompose and reducing the  
49  
50  
51 271 number of organic substances available for subsequent short-chain fatty acid production  
52  
53  
54 272 (Xu et al. 2020). The inconsistent observations regarding the impact of humic  
55  
56  
57 273 substances on the acidification stage of anaerobic digestion likely arose from  
58  
59  
60 274 differences between the structure, molecular weight, and functional group content, such

1 275 as phenolic group and carboxyl group of the humic substances. The commercial humic  
2  
3 276 substances separately adopted by Liu et al. (2015) and Li et al. (2019b) enhanced short-  
4  
5  
6 277 chain fatty acids to varying degrees, which was ascribed to differences in the molecular  
7  
8  
9 278 weight and chemical structure of the humic substances. In addition, the maximum short-  
10  
11  
12 279 chain fatty acids were obtained with different concentrations of humic substances (1120  
13  
14 280 versus 150 mg humic substances/g volatile solids) and functional group contents, i.e.,  
15  
16  
17 281 phenolic group and carboxyl group, leading to differences in both the quinone structure  
18  
19  
20 282 number in humic substances and the bioconversion of organic substances to short-chain  
21  
22  
23 283 fatty acids (Li et al. 2019b; Liu et al. 2015).

### 27 284 3.3 Methanogenesis stage

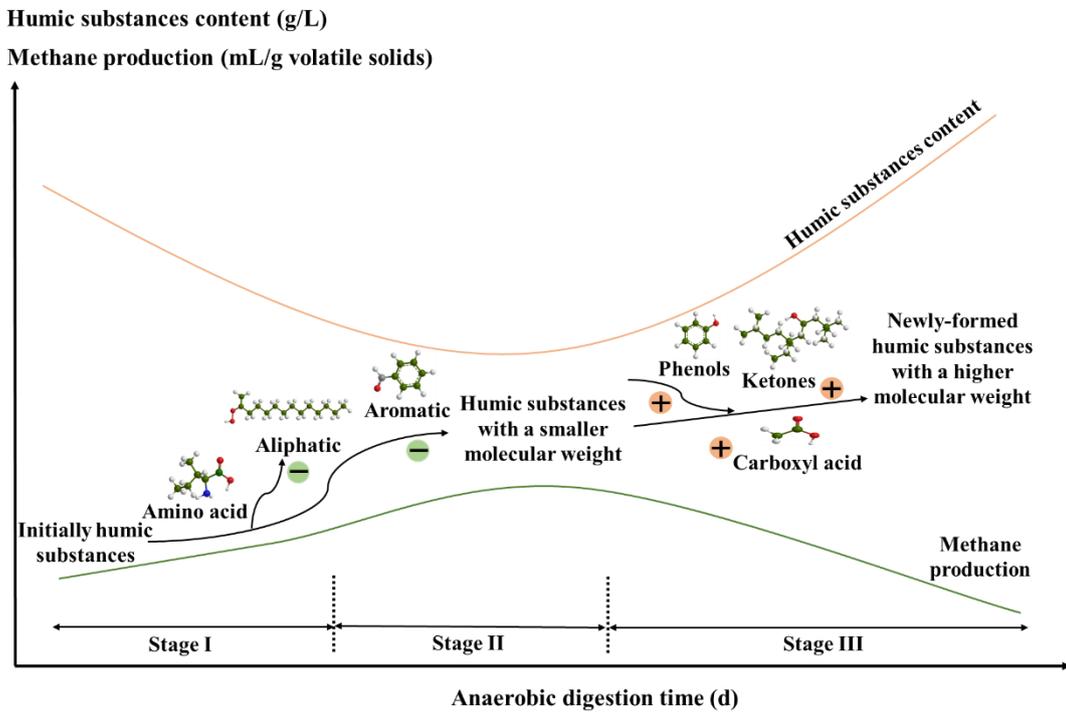

31 285 Many studies have found that the addition of humic substances inhibits methane  
32  
33 286 production in anaerobic digestion (Azman et al. 2017; Li et al. 2019b; Liu et al. 2015;  
34  
35  
36 287 Wang et al. 2022a; Xu et al. 2020). For instance, methane production was severely  
37  
38  
39 288 inhibited by 14% to 97% when the SHHA levels were increased from 430 mg humic  
40  
41  
42 289 substances/g volatile solids to 1430 mg humic substances/g volatile solids (Liu et al.  
43  
44  
45 290 2015). This inhibition was mainly caused by the competition of humic substances with  
46  
47  
48 291 acetoclastic methanogens for electrons, severely inhibiting acetoclastic methanogen  
49  
50  
51 292 activity and the bioreaction of acetyl-CoA to yield 5-methyl-tetrahydromethanopterin  
52  
53  
54 293 (Liu et al. 2015). Azman et al. (2017) observed a similar inhibition effect but attributed  
55  
56 294 the lower methane yield to lower activity of hydrogenotrophic methanogens, such as  
57  
58  
59 295 *Methanobacteriaceae*, *Methanomicrobiales*-WCHA208, and Unassigned

1 296 *Thermoplamata* WCHA1-57 rather than that of acetoclastic methanogens, due to the  
2  
3 297 lower acclimatization capacity of the hydrogenotrophic methanogen microbial  
4  
5  
6 298 community with the addition of humic substances. Li et al. (2019b) found that the  
7  
8  
9 299 methanogenic efficiency decreased by 52.2% after adding 150 mg humic substances/g  
10  
11 300 volatile solids, which may have been due to lower F420 activity (a key enzyme in  
12  
13 301 methane biosynthesis), competition between humic substances and acetate for electrons,  
14  
15 302 and blocking between humic substances and methanogens for metabolites. In addition,  
16  
17 303 Xu et al. (2020) found that a reduced methane yield with humic substances addition  
18  
19 304 was due to humic substances changing the bioaccessibility of hydrolysis products,  
20  
21 305 which resulted in poor bioconversion from glucose to biogas.  
22  
23  
24  
25  
26  
27  
28  
29  
30 306 Nonetheless, controversial outcomes have been reported in some studies. Huang et al.  
31  
32 307 (2021) found that methanogenesis was enhanced approximately two-fold, and  
33  
34 308 coenzyme F420 activity increased by 19% under 10 mg humic substances/g volatile  
35  
36 309 solids conditions. The enhanced enzyme activity might have been caused by small  
37  
38 310 molecular weight humic substances passing through the cell membranes of anaerobes  
39  
40 311 and enhancing electron transfer capacity. This result was further confirmed by Zhao et  
41  
42 312 al. (2023a), in that study, small molecular humic substances acted as electron donors,  
43  
44 313 accelerating the electron transport capacity of methanogens and resulting in a 15.8–  
45  
46 314 80.8% enhancement of methane production. Noteworthy, the promotion effect of humic  
47  
48 315 substances on methane production was observed during the thermal hydrolysis  
49  
50 316 pretreatment of sludge which caused the variation of the humic substances molecular  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60  
61  
62  
63  
64  
65

1 317 structure, including carbon/nitrogen ratio, functional group, elemental composition, and  
2  
3 318 E4/E6 ratio of humic substances (Huang et al. 2021; Zhao et al. 2023a). Additionally,  
4  
5  
6 319 the low concentration of humic substances adopted in those studies has also been found  
7  
8  
9 320 to play a key role in facilitating methane production. However, in traditional wastewater  
10  
11  
12 321 treatment plants, secondary sludge does not undergo thermal hydrolysis pretreatment  
13  
14  
15 322 before entering anaerobic digestion reactors due to high energy demand, which  
16  
17  
18 323 increased the operating costs of the wastewater treatment plants, and the concentration  
19  
20  
21 324 of humic substances in the secondary sludge is typically much higher than the  
22  
23  
24 325 concentration required to promote methane production (0.2-0.3 g/g volatile solids  
25  
26  
27 326 (humic substances content in secondary sludge) versus 0.05 g/g volatile solids (the  
28  
29  
30 327 adopted humic substances concentration that observed to enhance the methane  
31  
32  
33 328 production after the pretreatment of secondary sludge)).

34  
35  
36 329 Taken together, it can be concluded that the high concentration of humic substances in  
37  
38  
39 330 the secondary sludge (far higher than the concentration of humic substances required  
40  
41  
42 331 for promoting methane production) has a negative impact on the performance of  
43  
44  
45 332 anaerobic digestion in the traditional wastewater treatment plants. Based on this,  
46  
47  
48 333 measures need to be taken to alleviate the inhibitory effects of humic substances on  
49  
50  
51 334 anaerobic digestion and improve its overall efficiency. A deeper understanding of the  
52  
53  
54 335 dynamic evolution of humic substances during anaerobic digestion is crucial in  
55  
56  
57 336 formulating strategies to mitigate their inhibitory effects on the process. In the  
58  
59  
60 337 following sections, we will first discuss the dynamic evolution of humic substances and

338 then explore strategies to mitigate their inhibitory effects.

339

340 **Figure 3.** Dynamic evolution of humic substances in anaerobic digestion. Note: Stage

341 I, stage II, and stage III represent the consumption of labile aliphatic and exposure of

342 aromatic in humic substances, biodegradation of labile aromatic structure in humic

343 substances, and repolymerization of humic substances, respectively. The minus sign in

344 the green circle and the plus sign in the orange circle mean depolymerization and

345 repolymerization, respectively. The distribution of humic substances in liquid and solid

346 phase affect anaerobic digestion efficiency, and the repolymerisation of humic

347 substances in anaerobic digestion reduces sludge degradability.

#### 348 4. Evolution of humic substances during anaerobic digestion

349 Studying the dynamic evolution of humic substances in anaerobic digestion processes

1 350 helps to provide an in-depth understanding of their behavior and influencing factors in  
2  
3 351 anaerobic digestion reactors, thereby benefiting to development and implement  
4  
5  
6 352 strategies that improve the overall performance of anaerobic digestion. Variations of  
7  
8  
9 353 the humic substances' content and structure have been commonly reported during the  
10  
11  
12 354 anaerobic digestion process. The dynamic evolution of humic substances during  
13  
14  
15 355 anaerobic digestion typically passes through three phases (Tang et al. 2018) (Fig. 3): 1)  
16  
17 356 superficial labile aliphatics are extensively consumed by microorganisms as energy  
18  
19  
20 357 sources, causing aromatic exposure that enhances the aromaticity of humic substances;  
21  
22  
23 358 2) some labile aromatic structures in humic substances are further biodegraded by  
24  
25  
26 359 anaerobes; and 3) more stable and unsaturated humic substances structures form due to  
27  
28  
29 360 the repolymerisation of humic substances with new aromatics. The variations of the  
30  
31  
32 361 specific content and structure of humic substances in anaerobic digestion are discussed  
33  
34 362 in detail in the following sections.

#### 35 36 37 38 363 4.1 Evolution of humic substances content

39  
40  
41  
42 364 Several studies have demonstrated *in situ* biosynthesis, degradation, and  
43  
44  
45 365 repolymerisation of humic substances during anaerobic digestion (Dai et al. 2013; Li et  
46  
47  
48 366 al. 2013; Wang et al. 2021b). For example, Li et al. (2013) not only revealed that humic  
49  
50  
51 367 substances were the key components of extracellular polymeric substances but also  
52  
53  
54 368 found that they emerged in microbe cells. Dai et al. (2013) observed that the humic  
55  
56  
57 369 substances content in digested sludge (30.1%) was higher than that in raw secondary  
58  
59 370 sludge (20.0%), indicating the generation of humic substances during anaerobic

1 371 digestion, where humic substances content augmentation was attributed to the  
2  
3 372 transformation of protein-like substances. Wang et al. (2021b) confirmed the  
4  
5  
6 373 simultaneous degradation and repolymerisation of humic substances in anaerobic  
7  
8  
9 374 digestion, as the humic substances content first decreased from 8.4 g/L to 4.6 g/L but  
10  
11  
12 375 then increased to 7.7 g/L during mesophilic anaerobic digestion. Liu et al. (2019a)  
13  
14 376 controversially observed that humic substances were not formed but rather degraded in  
15  
16  
17 377 anaerobic digestion. Specifically, the humic substances content in the anaerobic  
18  
19  
20 378 digestion system with humic substances-free sludge remained almost unchanged but  
21  
22  
23 379 decreased in the anaerobic digestion system with sludge from wastewater treatment  
24  
25  
26 380 plants. These conflicting observations might be attributed to two aspects: 1) the  
27  
28 381 complex composition of humic substances in real sludge had a high percentage of small  
29  
30  
31 382 molecular weight moieties and aliphatic moieties, which were oxidized in anaerobic  
32  
33  
34 383 digestion, leading to reduced humic substances content (Li et al. 2013); and 2) the  
35  
36  
37 384 organic loading rate of sludge from wastewater treatment plants was higher than that of  
38  
39  
40 385 humic substances-free sludge (0.077 mg/L versus 0.06 mg/L). This indicated that more  
41  
42 386 aliphatic moieties of humic substances could be oxidized, which may explain the  
43  
44  
45 387 inconsistency of humic substances variation (Liu et al. 2019a). Additionally, the  
46  
47  
48 388 distribution of humic substances in the solid and liquid phases during anaerobic  
49  
50  
51 389 digestion processes has been shown to vary significantly; the humic substances content  
52  
53 390 in the solid phase gradually decreased by 47.6%, while that in the liquid phase increased  
54  
55  
56 391 by 92.2% (Liu et al. 2019a). Tang et al. (2020b) similarly reported that 49% of humic  
57  
58  
59 392 substances were released from the solid to the liquid phase during anaerobic digestion.

1 393 The distribution of humic substances in solid and liquid phases, rather than the overall  
2  
3 394 humic substances content, are more likely to influence anaerobic digestion performance.  
4  
5  
6  
7

#### 8 395 4.2 Evolution of the humic substances structure 9

10  
11 396 Changes in the humic substances structure due to anaerobic digestion can be mostly  
12  
13 397 observed in three aspects: 1) increased humification degree of humic acid and fulvic  
14  
15 398 acid, as evidenced by augmented total acidity (phenolic and carboxyl moieties) (Liu et  
16  
17 399 al. 2019a); 2) degradation of aliphatic moieties by microorganisms due to their simple,  
18  
19 400 linear, and vulnerable structure, while aromatic moieties are subsequently more  
20  
21 401 exposed to the environment (El Fels et al. 2014; Wang et al. 2021b); and 3) the  
22  
23 402 repolymerisation of aromatic moieties in humic substances. Through repolymerisation,  
24  
25 403 organic compounds combine with aromatic moieties in humic substances through the  
26  
27 404 actions of enzymes and microorganisms to form more complex structures, which are  
28  
29 405 more difficult for bacteria to decompose and utilize. The repolymerisation of aromatic  
30  
31 406 moieties generally follows three main routes: 1) consumption of aliphatic moieties  
32  
33 407 conducive to transforming polysaccharides into other oxidized compounds (Liu et al.  
34  
35 408 2019a); 2) polymerization of non-humic substances or biodegradable fulvic acid with  
36  
37 409 humic substances aromatic structures (Awasthi et al. 2017); and 3) use of C=C in  
38  
39 410 aromatics from lignin to compose the basic structures of newly formed humic  
40  
41 411 substances (Zheng et al. 2014).  
42  
43  
44  
45  
46  
47  
48  
49  
50  
51  
52  
53  
54  
55  
56  
57

58 412 The anaerobic digestion process changes humic substances structures by increasing the  
59  
60  
61  
62  
63  
64  
65

1 413 molecular size and the amounts of aromatic structures and oxygen functional groups.  
2  
3 414 In an anaerobic digestion reactor, the ratio of oxygen/carbon was raised from 0.32 to  
4  
5  
6 415 0.39, while the ratio of carbon/nitrogen was reduced from 9.06 to 6.41, accompanied  
7  
8  
9 416 by an increase in humic substances total acidity from 2.32 mmol/g to 3.29 mmol/g (Li  
10  
11 417 et al. 2017b). The proportion of humic substances with average molecular weights over  
12  
13  
14 418 50 kDa and 100 kDa also rose from 14.7% to 18.4% and from 65.3% to 85.5%,  
15  
16  
17 419 respectively (Li et al. 2017b). Wang et al. (2021a) revealed that the contents of oxygen-  
18  
19  
20 420 containing and aromatic moieties after anaerobic digestion increased from 37% to 45%  
21  
22  
23 421 and from 41% to 66%, respectively, indicating augmented degrees of condensation and  
24  
25  
26 422 humification. Liu et al. (2019a) also observed that the variation in the humic substances  
27  
28  
29 423 structure was caused by the consumption of aliphatic moieties and the enrichment of  
30  
31  
32 424 aromatic moieties. Notably, the release of humic substances from the solid to the liquid  
33  
34  
35 425 phase during anaerobic digestion shows that it promotes humic substances  
36  
37  
38 426 solubilization. This phenomenon might be explained by the augmentation of oxygen-  
39  
40  
41 427 containing functional groups after anaerobic digestion, which improves the  
42  
43  
44 428 hydrophilicity of humic substances and thus enhances their solubility (He et al. 2023;  
45  
46  
47 429 Liu et al. 2019a).

431 **Table 2** Methods to mitigate the inhibition of anaerobic digestion by humic substances

Technologies	Conditions	Enhancement of biogas production	References
Pretreatment of secondary sludge before anaerobic digestion	140 mg calcium peroxide/g volatile solids	47.6%	Wang et al. (2019)
	78.91 mg calcium hypochlorite/g volatile solids	33.8%	Hu et al. (2022)
Addition of metal salts	5 mM calcium ion	128%	Azman et al. (2015)
	5 mM magnesium ion	146%	
	5 mM iron ion	145 %	
	100 mg/L calcium ion, 70 mg/L aluminium ion	Not available	
Addition of enzymes	Hydrolytic enzymes	Not available	Fernandes et al. (2015)
	Amylase	19%	Yu et al. (2013)
	Protease	16%	
	Amylase and protease	20%	
Introduction of endogenous or exogenous organisms	<i>Ochrobactrum</i> sp. POC9	20%	Poszytek et al. (2018)

1 433 **5. Strategies to mitigate the inhibition of anaerobic digestion by humic substances**

2  
3  
4  
5 434 To mitigate the inhibition effect of humic substances on anaerobic digestion  
6  
7  
8 435 performance, several methods have been adopted, including the removal of humic  
9  
10  
11 436 substances from wastewater, the pretreatment of secondary sludge before anaerobic  
12  
13  
14 437 digestion, the addition of metal salts to reduce humic acid binding ability, the addition  
15  
16  
17 438 of enzymes to bind with humic substances or promote humic substances decomposition,  
18  
19 439 and the introduction of endogenous or exogenous organisms to facilitate humic  
20  
21  
22 440 substances degradation (Table 2). The performance of each strategy is discussed in the  
23  
24  
25 441 following sections.

26  
27  
28  
29 442 **5.1 Removal of humic substances from wastewater**

30  
31  
32  
33 443 Researchers have developed numerous methods to remove humic substances from  
34  
35  
36 444 wastewater, including physicochemical treatments such as adsorption, filtration,  
37  
38  
39 445 advanced oxidation processes, electrochemical, and so on. (Algamdi et al. 2019; Sinha  
40  
41  
42 446 and Ghosal 2023; Yin et al. 2020; Zhang et al. 2021a). Humic substances removal can  
43  
44  
45 447 achieve high efficiencies, reaching up to 99% through adsorption using magnetic  
46  
47  
48 448 biochar at a lower pH of 3-4 (Zhang et al. 2021a), 94.5% via ultrafiltration membranes  
49  
50  
51 449 (graphene oxide-polyethersulfone) (Algamdi et al. 2019), 96% with the addition of  
52  
53  
54 450 TiO<sub>2</sub>/coconut shell powder (Sinha and Ghosal 2023), and 90% through electrochemical  
55  
56  
57 451 treatment (Yin et al. 2020). Additionally, biological treatments involving the use of  
58  
59  
60 452 enzymes responsible for humic substances degradation have also been investigated

1 453 (Zahmatkesh et al. 2017; Zhu et al. 2022). Notably, the incorporation of purified  
2  
3 454 peroxidase has shown great potential in achieving nearly complete elimination of humic  
4  
5  
6 455 substances from wastewater (Zhu et al. 2022). These methods have effectively removed  
7  
8  
9 456 humic substances from wastewater and reduced their accumulation in secondary sludge,  
10  
11  
12 457 thereby enhancing the subsequent anaerobic digestion efficiency of secondary sludge.  
13  
14 458 However, it is crucial to acknowledge the potential challenges associated with these  
15  
16  
17 459 approaches. Implementing physicochemical treatments usually demands substantial  
18  
19  
20 460 energy and chemical inputs, resulting in increased operational costs for wastewater  
21  
22  
23 461 treatment plants, posing economic challenges for large-scale applications (Rashtbari et  
24  
25  
26 462 al. 2020). Moreover, the stability of biological treatments employing enzymes for  
27  
28  
29 463 humic substances degradation can be affected by environmental factors, leading to  
30  
31  
32 464 fluctuations in microbial activity (Zhu et al. 2022). Although these extraction  
33  
34  
35 465 approaches can be successfully applied at the laboratory scale, their practical and  
36  
37  
38 466 economic feasibility in pilot or full-scale applications remains questionable due to  
39  
40  
41 467 extremely high operational costs.

## 44 468 5.2 Pretreatment of secondary sludge before anaerobic digestion

47  
48 469 Pretreatment of secondary sludge means the addition of compounds with high oxidation  
49  
50  
51 470 capacities, such as calcium peroxide, calcium hypochlorite, sodium perborate in terms  
52  
53  
54 471 of enhancing the biodegradation of humic substances (Hu et al. 2022; Millati et al.  
55  
56  
57 472 2020). These compounds can destroy the structures of humic substances, leading to a  
58  
59  
60 473 reduction of polymerization and generating biodegradable organic matter with small

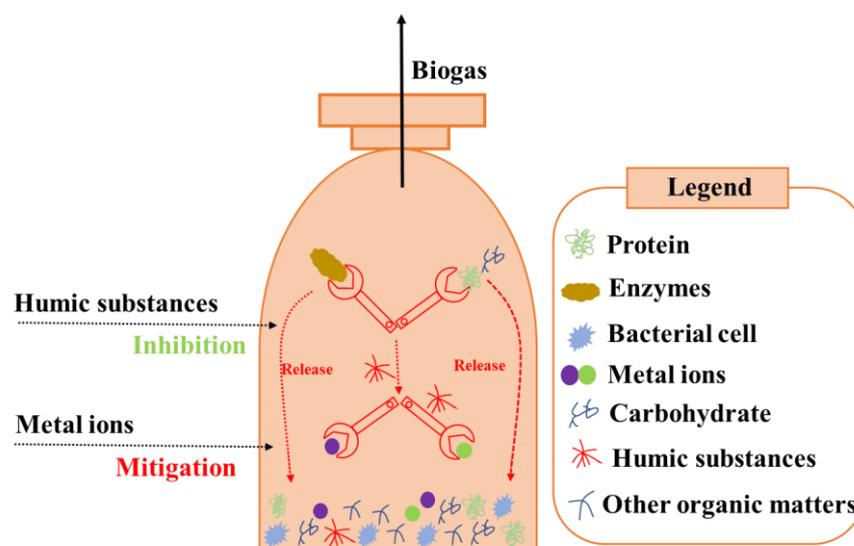

1 474 molecular weights. For example, the pretreatment of secondary sludge with calcium  
2  
3 475 peroxide (0.14 g/g volatile solids) enhanced methane production by 47.6%, which was  
4  
5  
6 476 mainly attributed to the degradation of humic substances and the generation of  
7  
8  
9 477 biodegradable organic substances (Wang et al. 2019b). Calcium hypochlorite (78.91  
10  
11 478 mg/g volatile solids) pretreatment of secondary sludge enhanced methane production  
12  
13  
14 479 by 33.8%, partly due to enhanced humic substances biodegradability, and reduced the  
15  
16  
17 480 humic substances concentration (Hu et al. 2022). Studies have also shown that sodium  
18  
19  
20 481 perborate, peracetic acid, and ozone improved humic substances degradation (Ai et al.  
21  
22 482 2019; Ding et al. 2019; Yin et al. 2011). However, compounds with high oxidation  
23  
24  
25 483 capacities not only degrade humic substances in sludge but also other soluble organic  
26  
27  
28 484 substances, resulting in the oxidation of many soluble organic substances to carbon  
29  
30  
31 485 dioxide and ultimately providing fewer organic substances to anaerobes for subsequent  
32  
33  
34 486 biogas production. Also, the high prices of these compounds have limited their  
35  
36  
37 487 application.

### 41 488 5.3 Addition of metal salts

42  
43  
44  
45 489 A variety of metal salts, such as calcium, magnesium, iron, and aluminum, have been  
46  
47  
48 490 added to anaerobic digestion to alleviate the inhibition caused by humic substances,  
49  
50  
51 491 with potential mechanisms shown in Fig. 4. The individual addition of calcium,  
52  
53  
54 492 magnesium, or iron salts greatly reduced the inhibition of humic substances on  
55  
56  
57 493 hydrolysis, with hydrolysis efficiencies increasing by 65%, 75%, and 72%, respectively  
58  
59 494 (Fernandes et al. 2015). The corresponding methane production was also enhanced by

1 495 128%, 146%, and 145% compared with the respective group without added metal salts  
2  
3 496 (Fernandes et al. 2015). This might be attributed to the presence of diverse functional  
4  
5  
6 497 groups, i.e., carboxylic, ketones, phenols in humic substances in sludge, which provide  
7  
8  
9 498 superior metal-binding abilities through complexation and adsorption reactions (He et  
10  
11  
12 499 al. 2016). Interestingly, the addition of sodium and potassium salts did not significantly  
13  
14 500 mitigate the inhibition of humic substances on hydrolysis efficiency, which might due  
15  
16  
17 501 to the lower complexation ability of sodium and potassium salts with humic substances  
18  
19  
20 502 (Azman et al. 2015). The addition of 100 mg/L calcium or 70 mg/L aluminum salts  
21  
22 503 greatly reduced the inhibition of humic substances on hydrolysis efficiency by up to  
23  
24  
25 504 65%, which was likely caused by the binding of metal salts with humic substances  
26  
27  
28 505 through sweep flocculation, cation exchange, and electrostatic forces (Li et al. 2021).  
29  
30  
31 506 The binding of metal salts to humic substances reactivated hydrolytic enzymes and  
32  
33  
34 507 eventually increased the degradation of organic substances in anaerobic digestion (Li  
35  
36  
37 508 et al. 2021). Furthermore, synergistic effects in alleviating inhibition by humic  
38  
39 509 substances can be achieved by the joint addition of two metal ions at low concentrations.  
40  
41  
42 510 Specifically, the addition of calcium at 50 mg/L and aluminum salt at 10 mg/L restored  
43  
44  
45 511 80% of hydrolysis efficiency in anaerobic digestion in the presence of humic substances  
46  
47  
48 512 (Li et al. 2021). These studies have shown that metal salt addition can mitigate  
49  
50  
51 513 inhibition by humic substances in the hydrolysis stage, and the enhancement of  
52  
53  
54 514 hydrolysis efficiency increases the availability of soluble organic substances to  
55  
56 515 anaerobes for subsequent methane bioproduction.  
57  
58  
59  
60  
61  
62  
63  
64  
65

516 Notably, humic substances bind more effectively to heavy metal ions, such as mercury,  
 517 cadmium, copper than to the other metal ions mentioned above, i.e., aluminum, calcium,  
 518 magnesium, and iron (Zhao et al. 2023b). However, the addition of heavy metal salts to  
 519 the anaerobic digestion system would pose an extreme risk to the ecosystem, such that  
 520 aluminum, calcium, magnesium, and iron are better options when using metal salts to  
 521 mitigate inhibition by humic substances on anaerobic digestion performance.

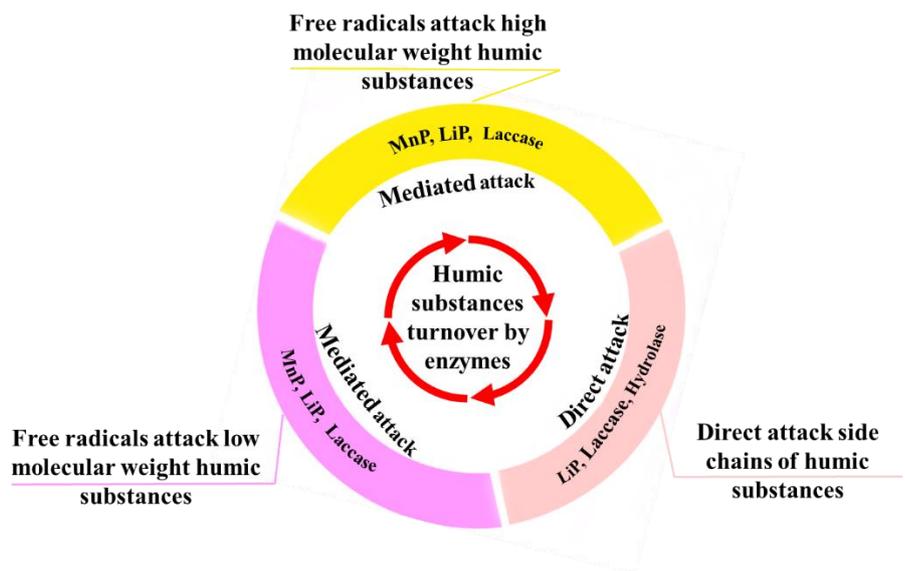

522 **Anaerobic digestion of secondary sludge**

523 **Figure 4.** Metal salts mitigate the inhibitory effect of humic substances on anaerobic  
 524 digestion performance. Metal salts can effectively reduce the inhibitory effect caused  
 525 by humic substances during anaerobic digestion.

#### 526 5.4 Addition of enzymes or the introduction of endogenous or exogenous organisms

527 The addition of hydrolytic enzymes, such as protease,  $\alpha$ -amylase, was shown to reduce  
 528 the negative influence of humic substances on anaerobic digestion performance (Fig. 5)  
 529 (Fernandes et al. 2015). This is to likely occur because additional hydrolytic enzymes

1 530 attach to humic substances, which prevents the interaction of humic substances with  
 2  
 3 531 intrinsic hydrolytic enzymes produced by anaerobes within the anaerobic digestion  
 4  
 5 532 process (Fernandes et al. 2015). A similar conclusion was also reached by Yu et al.  
 6  
 7  
 8 533 (2013), who observed that the addition of protease, amylase, and their combination  
 9  
 10  
 11 534 enhanced the yield of biogas, with values of 16%. 19% and 20%, respectively.

34 535  
 35  
 36  
 37 536 **Figure 5.** Proposed metabolic pathway of humic substances degradation and  
 38  
 39 537 transformation by enzymes. Note: MnP and LiP represent manganese peroxidase and  
 40  
 41 538 lignin peroxidase, respectively. Adding enzymes can enhance the degradation of humic  
 42  
 43 539 substances, benefiting anaerobic digestion efficiency.

44  
 45  
 46  
 47  
 48  
 49  
 50 540 Laccase, manganese peroxidase, and lignin peroxidase facilitated the degradation and  
 51  
 52 541 transformation of humic substances (proposed model shown in Fig. 5) (Negi and Das  
 53  
 54 542 2023). These enzymes mainly attack humic substances along three pathways: 1) direct  
 55  
 56 543 attack on the side chains by laccases and lignin peroxidase; 2) mediated attack on high

1 544 molecular weight humic substances by free radicals, resulting in the generation of low  
2  
3 545 molecular weight humic substances; and 3) mediated attack on the low molecular  
4  
5  
6 546 weight humic substances by free radicals, resulting in their degradation, incorporation,  
7  
8  
9 547 mineralization, and polymerization. For example, the addition of laccase transformed  
10  
11  
12 548 humic substances into several small molecular substances, such as fulvic acid, and  
13  
14 549 humic acid (Lisov et al. 2021; Zahmatkesh et al. 2016). Such humic substances with  
15  
16  
17 550 small molecular weights can pass through the cell membranes of anaerobes, enhancing  
18  
19  
20 551 the efficiency of electron transfer capacity and methane yield and eventually relieving  
21  
22  
23 552 the inhibition of anaerobic digestion processes by humic substances (Huang et al. 2021).  
24  
25 553 In addition, manganese peroxidase and lignin peroxide can also catalyze the  
26  
27  
28 554 depolymerization of humic substances into substances with small molecular weights  
29  
30  
31 555 (Zhang et al. 2022a). However, enzyme activity is influenced by many factors, i.e.,  
32  
33  
34 556 temperature, pH, humic substances concentration, and enzymes are generally expensive,  
35  
36  
37 557 which limits their application in the real world.  
38  
39  
40  
41 558 Organisms associated with hydrolysis and methanogenesis may also overcome the  
42  
43  
44 559 inhibition of humic substances, owing to the production of enzymes or repair of their  
45  
46  
47 560 membranes. As a result, these microorganisms can tolerate high concentrations of  
48  
49  
50 561 humic substances and avoid their negative impact on the performance of anaerobic  
51  
52  
53 562 digestion (Yap et al. 2018). The presence of humic substances in anaerobic digesters  
54  
55  
56 563 has been found to be positively correlated with organisms belonging to *Actinomycetales*,  
57  
58 564 *Syntrophobacterales*, *Pedosphaerales*, and *Methanosaeta*. These organisms may be  
59  
60  
61  
62  
63  
64  
65

1 565 considered a potential candidate for the bioaugmentation of the sludge exposes to humic  
2  
3 566 substances (Yap et al. 2018). Poszytek et al. (2018) reported that the bioaugmentation  
4  
5  
6 567 of *Ochrobactrum* sp. POC9 in secondary sludge, remarkably enhanced the performance  
7  
8  
9 568 of anaerobic digestion, resulting in a 20% enhancement of methane production. The  
10  
11  
12 569 effectiveness of the bioaugmentation strategy exposed to high concentrations of humic  
13  
14  
15 570 substances in anaerobic digestion has not been extensively studied. However,  
16  
17  
18 571 introducing exogenous anaerobic organisms that are tolerant to humic substances or  
19  
20  
21 572 have the capability of degrading them, maybe a promising alternative to overcome the  
22  
23  
24 573 inhibition of anaerobic digestion caused by humic substances, especially when  
25  
26  
27 574 endogenous organisms cannot adapt to the presence of humic substances. For instance,  
28  
29  
30 575 Li et al. (2019a) reported a phenomenon where long-term acclimatization of secondary  
31  
32  
33 576 sludge to the high concentration of humic substances (the ratio of humic substances and  
34  
35  
36 577 volatile solids was 20%) did not result in the adaptation of the microbial community to  
37  
38  
39 578 humic substances and therefore did not enhance the performance of anaerobic digestion.  
40  
41  
42 579 On the contrary, anaerobic digestion efficiency decreased by 74%.

## 43 44 580 **6. Perspective**

45  
46  
47  
48  
49 581 The presence of humic substances makes the sludge structure denser and more compact,  
50  
51  
52 582 resulting in fewer organic substances bioavailable for subsequent anaerobic digestion  
53  
54  
55 583 (He et al. 2016; Xu et al. 2020). Unfortunately, few studies have focused on mitigating  
56  
57  
58 584 the impact of humic substances on the sludge structure. While extensive studies have

1 585 investigated humic substances removal from wastewater, including adsorption  
2  
3 586 (Sountharajah et al. 2015), membrane filtration (Ma et al. 2010), electrochemical  
4  
5  
6 587 treatment (Shan et al. 2016), and enzymatic treatment (Zahmatkesh et al. 2017), such  
7  
8  
9 588 methods have limited application in the real world due to their high costs (Zhu et al.  
10  
11  
12 589 2022). Therefore, more attention should be given to exploring cost-effective methods  
13  
14 590 of removing humic substances from wastewater before it enters biological treatment  
15  
16  
17 591 processes in wastewater treatment plants. Additionally, organic substances in secondary  
18  
19  
20 592 sludge contain biodegradable organic substances and recalcitrant organic matter, but  
21  
22  
23 593 the degree of hydrolysis is typically evaluated only by the variation of biodegradable  
24  
25  
26 594 organic substances, while the recalcitrant organic matter is not included (Lu et al. 2020).  
27  
28 595 Pretreatment has been extensively and effectively adopted to promote anaerobic  
29  
30  
31 596 digestion efficiency (Li et al. 2016). For example, the humic substances content  
32  
33  
34 597 changed from 33.3% to 23.1%, from 36.2% to 15.9%, and from 29.4% to 10.5% with  
35  
36  
37 598 the pretreatment of sodium percarbonate (Wang et al. 2022b), heat-CaO<sub>2</sub> (Liu et al.  
38  
39 599 2019b), and sulfite (Liu et al. 2020), respectively. Therefore, recalcitrant organic matter  
40  
41  
42 600 variation is also needed as an index to describe the changes in organic substances in  
43  
44  
45 601 sludge and thus comprehensively and accurately represent the degree of hydrolysis.

46  
47  
48  
49 602 The repolymerisation of aromatic moieties in humic substances tends to generate humic  
50  
51  
52 603 substances with a larger molecular size, more aromatic structures, and oxygen  
53  
54  
55 604 functional groups, and less biodegradability to anaerobes (Awasthi et al. 2017; Zheng  
56  
57  
58 605 et al. 2014). Although phenol oxidases play an important role in the repolymerisation  
59  
60

1 606 of humic substances (Nozhevnikova et al. 2019), no relevant research has explored the  
2  
3 607 reduction of phenol oxidase activity in the anaerobic digestion of sludge to inhibit the  
4  
5  
6 608 repolymerisation of humic substances. Therefore, more research should investigate the  
7  
8  
9 609 inhibition of phenol oxidase activity and prevention of humic substances  
10  
11 610 repolymerisation.

12  
13  
14  
15  
16 611 Inconsistent observations regarding the impact of humic substances on each stage of  
17  
18  
19 612 anaerobic digestion, such as hydrolysis, acidification, and methanogenesis, may be  
20  
21  
22 613 attributable to the different sources, structures, molecular weights, functional groups,  
23  
24  
25 614 and concentrations of humic substances across studies (Huang et al. 2021; Liu et al.  
26  
27 615 2015). Some have reported that humic substances can act as electron acceptors, which  
28  
29  
30 616 can compete for electrons with methanogens and thus lead to the inhibition of methane  
31  
32  
33 617 production (Tan et al. 2017). However, humic substances can also act as electron donors  
34  
35  
36 618 that accelerate electron transfer capacity and enhance methane production (He et al.  
37  
38  
39 619 2019; Xiao et al. 2019). The role of humic substances as electron donors or acceptors  
40  
41 620 has been found to depend on the oxygen-containing groups and nitrogen content in  
42  
43  
44 621 humic substances (Wang et al. 2022a). For example, thermal hydrolysis pretreatment  
45  
46  
47 622 significantly changed the humic substances structure, i.e., E4/E6 ratio and  
48  
49  
50 623 carbon/nitrogen ratio in sludge, which augmented methane production by 200% (Huang  
51  
52  
53 624 et al. 2021). Noteworthy, the promotion effect of humic substances on anaerobic  
54  
55  
56 625 digestion occurred in the pretreatment of secondary sludge, i.e., thermal hydrolysis, and  
57  
58 626 with low concentration, i.e., 0.05 g/g volatile solids of humic substances added to  
59  
60

1 627 anaerobic digestion reactors. However, this phenomenon is rare in actual wastewater  
2  
3 628 treatment plants due to the complex structure of humic substances, i.e., low E4/E6 ratio,  
4  
5  
6 629 high carbon/nitrogen ratio, and the high concentration (0.2-0.3 g/g volatile solids) of  
7  
8  
9 630 humic substances in the secondary sludge. Therefore, humic substances present an  
10  
11 631 inhibitory effect on the efficiency of secondary sludge anaerobic digestion in traditional  
12  
13  
14 632 wastewater treatment plants. Thus, future studies should aim to enhance the electron-  
15  
16  
17 633 donating capacity of humic substances by altering the ratio of E4/E6 and  
18  
19  
20 634 carbon/nitrogen. This can help to reduce the binding of humic substances with enzymes  
21  
22  
23 635 and provide more electrons for methanogens, ultimately leading to improved  
24  
25  
26 636 performance of anaerobic digestion. Additionally, most previous studies have been  
27  
28  
29 637 performed in batch experiments (Li et al. 2017b; Li et al. 2019b). Future investigations  
30  
31  
32 638 are required to better understand the long-term effects of humic substances on the  
33  
34  
35 639 anaerobic digestion of secondary sludge in larger-scale applications and provide more  
36  
37  
38 640 crucial information for engineering applications.

39  
40  
41 641 Studies have reported several strategies to mitigate the inhibition of anaerobic digestion  
42  
43  
44 642 by humic substances, such as the removal of humic substances from wastewater, the  
45  
46  
47 643 pretreatment of secondary sludge before anaerobic digestion, the addition of metal salts,  
48  
49  
50 644 the addition of enzymes, or the introduction of endogenous and exogenous organisms  
51  
52  
53 645 (Li et al. 2014). The pretreatment of secondary sludge before anaerobic digestion has  
54  
55  
56 646 been limited by the high demand for energy, and chemicals. Alternatively, the addition  
57  
58  
59 647 of metal salts, such as calcium, magnesium, iron, and aluminum, seems to be a plausible

1 648 method to relieve the inhibition of anaerobic digestion by humic substances (Azman et  
2  
3 649 al. 2015; Li et al. 2021). However, the metal ion addition approach has been mainly  
4  
5  
6 650 applied at the laboratory scale (Azman et al. 2015). Pilot-scale and full-scale research,  
7  
8  
9 651 as well as investigations of the ecological impacts of metal ion addition, remain  
10  
11  
12 652 necessary. Moreover, adding enzymes requires the maintenance of optimal conditions  
13  
14  
15 653 for enzyme activity. However, in practical application, enzyme activity is often  
16  
17  
18 654 inhibited due to suboptimal conditions. Furthermore, the high cost of enzymes also  
19  
20  
21 655 limits their application. On the other hand, the introduction of exogenous anaerobes  
22  
23  
24 656 with the ability to degrade humic substances could be a promising method to overcome  
25  
26  
27 657 the inhibition of anaerobic digestion caused by humic substances. This can provide  
28  
29  
30 658 more substrates for subsequent anaerobic digestion processes, thereby facilitating  
31  
32  
33 659 anaerobic digestion efficiency. Further research is needed to explore the potential of  
34  
35  
36 660 this approach and determine the optimal conditions for introducing exogenous  
37  
38  
39 661 anaerobes into the anaerobic digestion system.

40  
41 662 In addition, various metabolic pathways of methane production in anaerobic digestion  
42  
43  
44 663 have been proposed to involve a range of enzymes and metabolites (Fig. 6) (Liu et al.  
45  
46  
47 664 2015; Zhang et al. 2020). Enzymes at various concentrations play a crucial role in  
48  
49  
50 665 methane production but are highly dependent on the microbial community. Microbes  
51  
52  
53 666 in sludge determine the secretion of relevant enzymes responsible for hydrolysis,  
54  
55  
56 667 acidification, and methanogenesis (Du et al. 2021; Liu et al. 2022; Liu et al. 2021).  
57  
58  
59 668 Although several studies have explored the responses of microbial communities to  
60  
61  
62  
63  
64  
65

1 669 diverse stress conditions, such as pH, temperature, salinity, the enrichment of  
2  
3 670 microorganisms communities varies significantly under different stress conditions. Few  
4  
5  
6 671 studies have focused on the influence of humic substances on microbial community  
7  
8  
9 672 evolution and the mechanism of regulation between enzymes and microbes (Tang et al.  
10  
11 673 2020b). Future studies are thus required to elucidate these phenomena, using molecular  
12  
13  
14 674 biology approaches combined with omics technology, such as genomics, proteomics,  
15  
16  
17 675 and transcriptomes to provide new insights regarding the mitigation of the inhibition  
18  
19  
20 676 effects of humic substances on anaerobic digestion performance.

681 tetrahydromethanopterin; fmdA, formyl-MFR dehydrogenase; ftr, formyl-MFR-THMPT formyltransferase; mch, methenyl-THMPT  
682 cyclohydrolase; mtd, 5,10-methylene-THMPY dehydrogenase; mer, methylene-THMPT reductase; ACDS, Acetyl-CoA decarboxylase; hdrA,  
683 heterodisulfide reductase; mcrA, methyl coenzyme reductase; and mtrA, THMPT methyltransferase. Clarifying the relationship between  
684 microorganisms and enzymes involved in the degradation of humic substances during anaerobic digestion processes is beneficial for promoting  
685 the degradation of humic substances.

1  
2 **686 7. Conclusion**  
3  
4  
5  
6

7 687 This review comprehensively summarises and presents insights into the effect of humic  
8  
9 688 substances on the performance of anaerobic digestion on secondary sludge. The key  
10  
11 689 findings of this review suggest that the presence of humic substances makes secondary  
12  
13 690 sludge denser and more compact, reducing the number of organic substances  
14  
15 691 bioavailable to anaerobes for subsequent anaerobic digestion. Moreover, the effect of  
16  
17 692 humic substances on each step of anaerobic digestion is case-specific and is determined  
18  
19 693 by several factors, including source, structure, molecular weight, and concentrations of  
20  
21 694 humic substances. However, in traditional wastewater treatment plants, the presence of  
22  
23 695 humic substances typically inhibits anaerobic digestion efficiency in traditional  
24  
25 696 wastewater treatment plants, due to the complex structure and high concentration in the  
26  
27 697 secondary sludge. Subsequently, the distribution of humic substances in the solid and  
28  
29 698 liquid phases affects anaerobic digestion efficiency, and the repolymerization of humic  
30  
31 699 substances during the anaerobic digestion process reduces the bioavailability of organic  
32  
33 700 substances, resulting in a stronger inhibitory effect on the performance of anaerobic  
34  
35 701 digestion. Increasing the E4/E6 ratio and decreasing the carbon/nitrogen ratio in the  
36  
37 702 molecule structure of humic substances can enhance their electron donor capacity and  
38  
39 703 lead to an improvement in anaerobic digestion efficiency by enhancing the electron  
40  
41 704 transfer capacity and methane production. Finally, the addition of metal salts and the  
42  
43 705 introduction of exogenous anaerobes are potentially effective in mitigating the  
44  
45 706 inhibition of anaerobic digestion caused by humic substances, with the former reducing
